THE first meeting of the session of the South Staffordshire Institute of Iron and Steel Works Managers was held on October 16, at Dudley. Mr. J. W. Hall, president, occupied the chair and delivered an inaugural address. He said that the Victorian era had been essentially the era of applied science, and that its most remarkable feature had been the extraordinary advance made in the material well-being of the people, more especially in that of our laboring population, by the employment of machinery which had rendered possible the production and distribution of the necessities and most of the luxuries of life at prices so remarkably low, combined with the simultaneous payment to the workers of wages so much higher than the world had ever seen before. This advance indicated that their hope of material prosperity in the future lay in still further development along the same path. It could only be by offering for sale to the inhabitants of the world articles produced by mechanical means, at a price and of a quality which would induce them to purchase, and to do this they must increase by every possible means the efficiency of their tools, and of their men who employed them. Their competitors abroad fully realized this fact, and were doing all they could to increase their manufacturing powers; and in the race for manufacturing supremacy, they were aspiring to sell to England what England formerly sold to them. The introduction of some new labor saving device might press hardly on the individual, but its use always eventually raised the scale of living of the community which employed it. The trades in which wages were lowest were those in which machinery had not yet come to the relief of the worker. Let machinery be introduced, and the product of the worker was so much increased that the half civilized handicraftsman had no chance against him. The world could now afford to pay to the man who worked the machine much more for his services, and so he was certain eventually to get more for his day's work. In the South Staffordshire district they would find that those branches of the iron trade which were carried on in small shops, unaided by power, were badly paid, or had totally disappeared before the employment of machinery elsewhere. There were men to-day who, in spite of all previous experience, seriously proposed, as a means of increasing the comfort of the workers, to limit as much as possible the efficiency of the workman or the machine which he tended. They took up the argument that the smaller the proportion of the work of the world which a man did, the larger would be his share of the world's income; the less his output, the greater his pay; and they seemed seriously to expect that a man could enjoy the benefits of the products of machinery without using it. It could not be too emphatically stated that upon England maintaining her manufacturing trade depended the material prosperity of the whole population. Should there be any material reduction in it, the first to suffer, and suffer most acutely, would be the workman: but it could not be too often pointed out

that there was not an inhabitant of these islands, let his trade, occupation, or profession be what it might, but would find his income sensibly diminished were any serious falling off to occur to English industries for any appreciable period. Privileged or monopolized trade was no longer possible; the "goodwill" of a business, once a valuable asset, had now almost disappeared. To supply the best article at the lowest possible price was the one qualification for success in the markets of the world to-day.—Colliery Guardian.

THE DISPOSAL OF GARBAGE AND REFUSE.*

THE subject upon which your committee was requested to make a report concerns the collection and disposal of the solid waste matter in cities, such as garbage, ashes, manufacturing refuse, etc. This branch of municipal work had heretofore not received satisfactory attention. There was much diversity of opinion regarding the proper methods to be pursued, and a basis upon which safe judgment could be founded did not as yet appear to exist.

It was, of course, impracticable for your committee to make any original investigations or experiments to enable it to solve the questions before it. Its work had to be confined to the collection of statistics, the inspection of works and the weighing of the evidence, and opinions of those directly engaged in the actual work of garbage and refuse collection and disposal.

In order to gather the needed information, circulars containing numerous questions were prepared and sent to 170 cities of the United States and Canada. The existing literature of the day was examined and visits of inspection were made, as was convenient, to the most important and instructive works of both Europe and America. By classifying, comparing and critically studying the information thus obtained, it became practicable to throw some useful light on the subject and to enable your committee to reach conclusions.

This information had been practically all compiled last year, and such of the results as were then apparent were reported at the last annual meeting. It was added then that, in view of certain forthcoming reports on some very thorough experiments, being conducted in the cities of Hamburg and Berlin, your committee did not deem it proper to present its own final report until after this European information had been obtained. Not until within the last few weeks did the documents reach this country. Their value, in the opinion of your committee, justifies the delay in concluding its own work, as without embodying these European results the committee's report would have failed to record the most complete, instructive, and valuable experiments on garbage and refuse destruction for large cities that have yet been published.

The collection and disposal of garbage and refuse must be considered, first, from a sanitary, and secondly, from a financial aspect. Satisfaction must be given in both respects; otherwise, as previously reported, the result will not be successful. "There may be a disposal which is entirely proper in a sanitary way, yet the expense may be so great that the method precludes general adoption. On the other hand, some cheap method of disposal may not comply with sanitary requirements, and can also not be recommended."

The solution of the problem depends upon the character and composition of the matter to be dealt with, upon the quantity to be handled, upon the necessary transportation to the place of disposal, upon the character of organization in charge of the work, and upon the ultimate disposition to be made of the material.

The best method of disposal will vary according to what can or must be done with the material. When it contains matter that may be converted into useful products, its disposition might properly differ from that which is necessary when it must be destroyed in a manner to prevent a nuisance or injury to health. Such utilization, when practicable, must be secondary in importance to a proper sanitary disposition. If the cost of disposal can be reduced by converting a part of the whole of the material into salable products, then utilization may be advocated for financial reasons, but only with the provision that a sanitary danger or nuisance is not created.

The best method of disposal, when the quantity of material is small, may also be different from when it is large; it will also depend upon whether it must be transported to a great distance or can be disposed of near the point where it is collected.

The questions of collection and disposal are, therefore, somewhat complex. From the variety of conditions which may govern the case, it will be seen that proper answers can only be given when the special conditions existing in each city or town are known. In the opinion of your committee, no single system of disposal can be recommended as being the best under all conditions.

This conclusion is further supported by the fact that the character of city refuse as collected differs materially in different countries, cities, and even in different parts of the same city. In some communities all refuse, namely, kitchen garbage, ashes and dry refuse from houses, factories, wharves, etc., is put into the same receptacles and delivered at the same point. In others, a separation is maintained of some of the materials, the food waste being collected in a different way and at different times from the dry refuse and ashes. In cities or parts of cities where no sewerage system exists, the night soil or human excrement is collected in special receptacles, and is disposed of sometimes separately, sometimes together with other refuse matter.

The terms garbage and refuse were defined by the committee as follows: By garbage is meant animal and vegetable waste matter subject to rapid decay, and collected from kitchens, markets, slaughter houses, etc., but not including night soil or street sweepings. By refuse is meant the miscellaneous material, comprising the dry waste matter from houses, stores, factories and streets, such as ashes, paper, straw, wood, rubbish, etc. These definitions are most commonly used throughout the country. In the Southern States, however, the term "garbage" is sometimes applied to dry refuse (Atlanta, Ga.) and to a mixture of dry refuse with animal and vegetable waste. In New England the word "swill" is more commonly used to designate kitchen waste, while in Pennsylvania and one or two other States "slop" is the name applied to it.

The present final report to a certain extent supplements the previous reports, but it contains all the conclusions which have heretofore been stated. The appendix contains the replies to circulars from over 150 American and Canadian cities, which constitutes a valuable mass of information concerning the status of the question in this country. It also contains descriptions of the most important methods of disposal in detail and of receptacles, carts, wagons, etc., which appear to have given fair satisfaction. It finally contains descriptions of the best European practice and the results thereof.

COLLECTION AND REMOVAL TO PLACE OF DISPOSAL.

The committee has found that in comparatively few places was there a careful and wise consideration given to the character of utensils, receptacles, carts or wagons, in which the refuse and garbage is collected. In most cases these articles are left to the judgment of house occupants or of contractors who collect the material.

No general recommendations can be given with reference to the character of the receptacles and wagons, because they should vary according to local conditions, and with the climate and method of final disposal. In cold countries, for instance, metal receptacles are not advantageous in the winter months, and wooden receptacles are preferred. The reverse is the case in hot climates. In all cases, however, they should be covered with a lid, and where cities give any directions at all with reference to these receptacles, this requirement is usually stated. Suitable cans for different conditions are described in the appendix.

Carts or wagons should be made of special design to suit the special conditions. Whether the garbage and refuse are collected in the same carts and wagons, or whether there is a separate collection, these carts and wagons should be covered. They should be covered with lids that can be easily opened and also firmly closed. They should be constructed of such shape that they can be easily and completely emptied of all their contents. Good designs for this purpose are found in use in some of our cities and are given in the appendix. It may be found economical, with certain cases of disposal, to have the carts so constructed that the boxes may be lifted off the wheels for dumping purposes. In some cases it may be preferable and less expensive to collect the material in large wagons drawn by two horses, while in other cases carts with single horses may be preferred. With the variety of designs that are in use, an intelligent selection of the most suitable design for given cases may be easily made.

Where the garbage is disposed of by dumping at sea, special scows and boats have been constructed for the purpose. The experience in Boston and New York City with such boats has probably developed the most suitable apparatus of this kind. The boats are so constructed that they can not only be readily loaded, but also can discharge the material by a single operation.

The collection of night soil from sections of the city not having sewers is usually accomplished by apparatus known as odorless excavators, and of these also there are several designs in the market which have proved satisfactory. The important features being an air-tight vessel, means of introducing the night soil by pumping through a special hose, and attachments for preventing the escape of noxious gases.

Regarding the frequency of collecting garbage and refuse, there seems to be no uniformity of practice, even in cities similarly situated. In some cases garbage proper is collected daily during the summer months; in most cases, however, but two or three times a week. Often the collection is more frequent in the densely populated portions than in the suburban districts of the city. It is the opinion of your committee that no difference should be made with reference to the density of population. Readily decomposing material should be removed as soon as possible after it has been offered for collection, as it will become odorous and objectionable equally as soon in the suburbs as in the center of the city. Decomposition is a question of time, not of locality. The frequency of collection should therefore depend on the season. It should, if possible, be collected daily in hot weather, at least three times a week in the spring and fall, and not less than twice a week in cold weather.

Ashes and dry refuse may be collected at all times once a week without objection, this being the usual practice. Refuse from business establishments or hotels must, in some cases, be removed more frequently on account of its rapid accumulation.

If garbage is collected daily, no decomposition should take place. Where it is collected less often in warm weather it is recommended that the receptacles, carts, wagons, etc., be disinfected and, if practicable, washed every time after they have been used. When garbage and dry refuse are removed together, the frequency of collection should be the same as though it were all garbage.

CHARACTER AND COMPOSITION.

Your committee has been able to secure but little information on the composition of garbage and refuse in the United States. In English and German cities this material has been frequently analyzed. In this country we have only secured one satisfactory statement, namely, from New York City. The analyses are given in the appendix.

The combined garbage and refuse in Germany differs from that in England by being poorer in combustible matter. English refuse contains more unburnt coal and also more waste organic matter. For this reason the products of combustion weigh but one-third of the original weight in England, and about one-half of the original weight in Germany.

In America, so far as ocular inspection goes, the ashes contain fully as much unburnt coal as in England, and decidedly more than in Germany. The quantity of kitchen garbage and combustible refuse is greater per inhabitant in America than in England, and still greater than in Germany. While the amount of organic matter in American garbage is greater, it is also true that in most cities it contains more moisture. The large quantity of vegetable and fruit refuse in our country probably causes this result.

American kitchen garbage contains from 2 to 4 per cent. of grease. European garbage contains somewhat less, i. e., from 1 to 3 per cent. From kitchen garbage about 5 per cent. of the original weight is left as ashes after combustion. When American garbage and dry refuse, including ashes, are mixed and burned, about one-fourth of the weight of the original mass remains as clinkers and ashes; in England one-third and in Germany one-half. It is therefore seen that three-fourths of the American mixed garbage, two-thirds of the English and only one-half of the German mixed garbage can be burned.

FINAL DISPOSAL.

The various ways in which garbage and refuse have been finally disposed of in American cities were mentioned in previous reports, and a few conclusions have already been drawn. In reviewing the subject, and with the recent evidence, particularly the above mentioned European reports before it, your committee can complete and sum up its conclusions as follows:

It has already been said that different conditions require different solutions. In view of this fact, a distinction must first be made as to whether the garbage is to be disposed of by individuals or by the community at large.

(A.) By Individuals.—If each householder must himself dispose of the garbage and refuse, as in the case of a country house or in a village, the following is recommended:

There appears to be no way in which this material can be properly and cheaply disposed of when the garbage is mixed with ashes and other refuse, and it is the opinion that in such cases it should be kept separated. There are several ways in which the most objectionable part, namely, the garbage, can be safely and properly disposed of. When it is fresh, and when nothing of a poisonous nature is added, then it can be safely fed to animals. In country houses this method is common. It is necessary, of course, that such feeding be confined to cases where proper intelligence can be exercised. The garbage from hotels is also very commonly sold for feeding, as it is profitable, and with proper care no objectionable results need follow. Where this method is not applicable, or where dangerous results are feared, there are but two other methods which your committee can indorse, namely, cremation and burial. To burn the garbage in the kitchen stove by throwing it upon the coals is often practiced, but is objectionable on account of the offensive odors which arise therefrom. Within a few years means have been provided and are in the market for carbonizing the garbage in the flue leading from the kitchen stove. This process, where applicable, can be well recommended. The garbage is slowly dried, then charred, and finally can be used for fuel, all without the discharge of any odors. Where this carbonizing is not undertaken, the only other safe alternative is a burial of the fresh garbage.

The remaining refuse of a country house consists of ashes, dry rubbish and perhaps also of night soil. In this case the latter is often converted on the premises into compost or manure and used upon the surrounding grounds. There can be no objection to such a method of disposal, if in case of certain sickness the night soil has been thoroughly disinfected. The disposal of ashes and rubbish will furnish no difficulties in the present case, as they can be dumped at an unobjectionable point on the premises or elsewhere.

(B.) By Communities.—The problem becomes a very different one when garbage and refuse must be collected from many buildings as in cities, and a common disposal provided. The quantities to be dealt with become large, and the control over the character of the material is lost. Other methods of disposal must, therefore, be resorted to, if sanitary as well as economical results are to be obtained.

In this case it becomes practicable either to combine all the various rejected materials or to keep them separated. A choice between the two methods will depend upon the local conditions and customs. In many cities, in nearly every European city, the garbage and dry refuse, including ashes, are all mixed, removed and disposed of together. In American cities they are combined in some cases and in others a separation of some of the material is made. Your committee is not able to state that either one or the other method is to be preferred in all cases. There may be instances where a separation is better and there may be others where the combined removal offers less difficulties and is less expensive.

(a) Separate Removal.—The fact that domestic garbage contains a fair percentage of grease, and that the remaining material may be converted into a fertilizer, has caused the development of processes in this country for converting garbage into these two materials to be sold at a profit. Such a method of disposal is applicable only in large cities. The works, which must be erected for this treatment of garbage, can only be profitable if large quantities are handled. Such works have been erected in a number of cities in the United States. Companies were formed, and the work was undertaken with the expectation of conducting a very profitable business. Experience has demonstrated, however, that in many instances there was no profit, and in others that it was small. It has heretofore been found impracticable to conduct the works so that a nuisance would be wholly prevented, and it was, therefore, found best to locate them at points where an occasional nuisance would not be objectionable. After several years operation a number of these works have been abandoned because, under the necessary sanitary restrictions, they were found not to be remunerative.

From a sanitary point of view, or as regards the creation of a nuisance, this process of disposing of garbage should be viewed with some suspicion. It should be allowed and, in the opinion of your committee, is only justifiable when the works are so located that a nuisance cannot possibly be created, and when it is also found to be cheaper to the community than cremation.

Experience has shown that in many cases this reduction process does not dispose of all the offensive material, and that it must be operated in conjunction with the cremation process, because some of the material collected with the garbage will neither yield grease nor make a good fertilizer, and is best disposed of by burning.

The latest and largest works for disposing of garbage by the reduction process have been built on Barren Island, where the garbage of New York and Brooklyn

* Report of the Committee of the American Public Health Association on the disposal of garbage and refuse, Rudolph Hering, M. Am. Soc. C. E., Chairman, at the annual meeting of the Association at Philadelphia, October 26, 1897.

is being treated. Contracts for this treatment were made within the last year or two, and it appears at the present time that the history of these works may possibly not differ much from the history of others. In this case, however, the distance from inhabited sections and the great quantities of material to be handled offer more favorable conditions for success than in most other cities. As the selling price of both the grease and the fertilizing residue has been steadily declining, it may probably be safely inferred that the profit of the reduction business does not meet the early expectations.

When the garbage is collected separately from the other refuse, then there remains another method for its disposal, which receives the commendation of your committee, namely, cremation. When garbage is separately collected, it contains from 50 to 80 per cent. of moisture. This fact has made its burning difficult. There is insufficient combustible material contained in the same to evaporate the large quantity of moisture contained in fresh garbage while burning up itself. For this reason it has been necessary to add coal to supply the heat in most of the American furnaces. They are nearly all so constructed that the wet material is thrown directly upon the grate bars. In the English furnaces the garbage and refuse are first thrown into an ante-chamber, where the material is dried before it reaches the grate bars. Your committee is not aware of the existence of a furnace constructed after the English pattern where garbage alone, without the addition of rubbish, ashes and cinders, has been consumed. It is, therefore, not in a position to state the actual results that would be found if garbage alone were burned in an English furnace. It seems, however, in view of the evidence before the committee, that it might be possibly found economical to subject garbage to a drying process before it is thrown upon the grate bars. With moderately wet garbage and suitably arranged apparatus it seems possible that the combustion might be effected with less coal than is now generally used. No intelligent experiments in this direction have, however, come to the attention of your committee, and no definite statement as to the economy of such a process can be given.

Besides the reduction of the kitchen garbage to grease and fertilizer, or its cremation, your committee is not able to designate any process by which the garbage of communities can be finally disposed of either economically or in a sanitary manner. If the garbage is disposed of separately there results the necessity of a separate disposal of the remaining material, consisting of ashes, cinders, rubbish, and dry combustible matter. Ashes and incombustible refuse can be safely wasted or dumped for filling in low ground. Dry combustible matter, of which large cities usually furnish a considerable amount, is best disposed of by being burnt in a crematory.

Your committee feels compelled to state, with reference to the disposal of these materials, that a separation does not seem to be economical or advisable, unless the conversion of garbage into salable products is an assured profitable business. It has not so been found in the larger cities of Europe, and separation is not there practiced.

(b) Combined Removal.—When no separation is made of the various waste materials and all are collected together, there is, in the opinion of your committee, but one way in which the final disposal should be accomplished; namely, by cremation. This is the system successfully adopted under these circumstances in many cities of Europe, and is growing in favor every year. (See statistics in appendix.) In England the burning of city garbage and refuse has been practiced in some cities for half a century. Considerable experience has, therefore, been gained regarding the most suitable construction of the furnaces and the manipulation of the material.

Within the last two years extensive experiments have been made in the cities of Hamburg and Berlin on the subject of garbage and refuse cremation, as already stated. The results there obtained with garbage that contains less combustible matter than the English and still less than the American garbage and refuse indicate, without any doubt, that a destruction of this material by fire can be an economical process, besides offering a thoroughly sanitary solution of the garbage question.

The European furnaces have not yet been introduced in America. Within a few years, however, a furnace resembling the English pattern, but apparently less efficient, has been erected in Montreal. The experience gained with it has been fairly satisfactory. The garbage and ashes are mixed, and they burn without the addition of fuel. It is found necessary, however, as was also found necessary in some cities of Europe, to sift the material and thus to free it from the fine ashes, which choke the fires.

Garbage in America contains more moisture than that in Europe, and this fact has made it appear as though cremating would not be as successful in this country; but your committee has reason to believe that the additional quantity of combustible material usually contained in the average American garbage more than compensates for this additional moisture, when the dry refuse and garbage are mixed. Without having a proper analysis at our disposal, we may say that to the eye there is no apparent difference in this respect between the mixed garbage and refuse of Europe and that of America.

In view of the results obtained during many years in England and lately obtained also in Germany, as fully given in the appendix to this report, there appears to be no reason why the same method of disposal, under the above mentioned limitations and conditions, should not be applicable to this country, by using properly constructed furnaces and having efficient workmen, thereby effecting a destruction of the material in a more sanitary way and probably also more economically than by other methods that have been tried.

Your committee finds that the recent reports from Hamburg, Zurich, and particularly the one from Berlin, have given material for a better understanding and judgment regarding the cremation of garbage than has been possible since the early English reports on the subject. A final report on similar experiments, with similar results recently gained in Paris, is also about to be issued.

The experience and results now before your committee indicate that the English pattern of cell furnaces with sloping ante-chamber for a preliminary drying and heating of the garbage give more economical results than the large and level American furnaces. It also plainly indicates that a skillful construction of the entire plant, and a skillful operation, requiring special training of the firemen, are prime requisites in obtaining successful results.

THE MICROBE OF YELLOW FEVER.*

I OWE the chance of the discovery of the microbe of yellow fever to the second case of the disease which presented itself to me at the island of Flores. This case, though it showed a mixture of various microbes, had, in a state of relative purity, the specific microbe, to which I have given provisionally the name of "bacillus icteroides," because yellow fever is known also under the name of typhus icteroides. I have said, "in a state of relative purity," because yellow fever is the prototype of the diseases of mixed infection. I have never found the "bacillus icteroides" alone in the autopsies I have made. It has been associated always with the micro-organisms previously referred to or among the numerous species of common microbes, or it has been impossible to find it because the other microbes, having entered the organism in its train, have ended by impeding its evolution and have even caused it to disappear entirely. The "bacillus icteroides" must be sought for in the blood and in the tissues, and not in the gastro-intestinal tube, in which, contrary to what might have been supposed à priori, I have never encountered it.

Upon the result of my investigations I will say that the isolation of the specific microbe of yellow fever is possible in only fifty-eight per cent. of the cases. The reasons for this are easy to understand. Before all, in the beginning of the disease, the "bacillus icteroides" multiplies very little in the human organism, a very small quantity of its toxin being sufficient to provoke in man the worst type of the disease. In the second place, the toxin, whether by itself or indirectly through the profound lesions it causes, especially in the digestive mucous membrane and in the liver, facilitates in an extraordinary manner every sort of secondary infection. According to my investigations, the "bacillus icteroides" is found in the circulating blood and in the tissues; the germ of yellow fever does not reside in the digestive tube, and its poison, instead of being absorbed through the intestinal walls, is fabricated in the interior of the organs and in the blood.

Morphologically this bacillus does not present at first sight anything characteristic. It is a little rod, with rounded extremities, united at best by pairs in cultures and in groups in the tissues, from two to four micromillimeters in length, and generally two or three times longer than it is broad. It is sufficiently polymorphous. Even in the cases that give the best results from the bacteriological examination, it is not easy to place the bacillus in evidence in sections of the tissues, on account of its extremely small number. In spite of this, by using the utmost care, one can find it in the organs, united usually in small groups and situated always in the minute capillaries of the liver, the kidneys, etc. Different modes of evolution can be used for diagnosis by exposing cultures, first for from twelve to sixteen hours to the temperature of the incubator, and afterward for other twelve to sixteen hours to the temperature of the air. This done, the colonies show themselves to be constructed with a flat central nucleus, transparent and azure, having a peripheral circle prominent and opaque. This peculiarity, which may be considered specific, may be made evident in less than twenty-four hours, serving to establish the bacteriological diagnosis of the "bacillus icteroides." Apart from this morphological characteristic, which suffices of itself to differentiate the microbe of yellow fever from all others previously known, the "bacillus icteroides" is endowed with some interesting biological qualities.

Once isolated, the exact bacteriological diagnosis of the bacilli does not require more than twenty-four hours. The disease is transmitted experimentally even by the respiratory tract to rabbits and guinea-pigs; the bacteriological examination of these cases shows, at least, the existence of a toxic process identical with that which takes place in man. It is then possible that the contagion of the virus of yellow fever may be effected even by means of the air, which is in accord with the dominant opinions in this respect. Up to the present time almost every sort of means has been tried in order to transmit yellow fever experimentally. These attempts gave no results, which explains why for many years the conviction has prevailed in the United States that this terrible malady was not contagious.

My experiments upon man reach the number of five. For reasons easily understood I have not used living cultures, but simple cultures in broth from fifteen to twenty days old, filtered with the Chamberland filter and sterilized, moreover, with the greatest caution by a few drops of formic aldehyde. In two of the individuals I tried the effect of subcutaneous injections and in the other three that of intravenous injections. These fortunate experiments, though few in number, are sufficient to illuminate in a manner unhoped for all the pathogenic mechanism, so obscure and so badly interpreted until now, of yellow fever. The injection of the filtered culture in doses relatively small reproduces in man typical yellow fever. The fever, the congestions, the hemorrhages, the vomit, the fatty degeneration of the liver, the headache, the backache, the nephritis, the anuria, the uremia, the jaundice, the delirium, the collapse, in fine, all that conjunction of anatomical and symptomatic elements which constitute by their combination the indivisible basis of the diagnosis of yellow fever, I have seen unroll before my eyes, thanks to the potent influence of the yellow fever poison made in my artificial cultures. This fact not only represents very valuable evidence in favor of the specific nature of the "bacillus icteroides," but it establishes new grounds for the etiological and pathological conception of yellow fever.

For the rest, the tenacious resistance to desiccation and to water I have found in the "bacillus icteroides" authorize me to admit that the diffusion of the virus of yellow fever can take place as well by air as by water. The experiments on animals show that infection by the respiratory tract is possible. With respect to the mechanism of infection by the way of fluids, a fact beyond doubt is that when the epithelium of the digestive tract is intact, in general it does not permit the entrance of any sort of pathogenic germ.

For a year, by work often interrupted, I have had the fortune to bring to this point our knowledge of this terrible infirmity, which represents the most grave and urgent sanitary problem throughout America. The ground covered is without doubt wide, but there remains yet much to go over. We have learned to know the specific agent of yellow fever; we have it in our power; we have studied minutely its life, its habits, its wants, its relations to external agents and to other small organisms; we have revealed the complicated mechanism of all the infinite manifestations which this agent determines in the human organism, and we have finally placed this disease, which a few months ago was a horrible mystery, on the same level as that occupied by the other great infectious diseases.

* From an address delivered by Giuseppe Sanarelli, M.D., at Montevideo, June 10, 1897, printed in the Medical Record, New York. Translated by A. C. H. Russell.

THE STRUCTURE OF BACTERIA.

THE actual intimate structure of micro-organisms is a subject which has as yet received but little attention from English bacteriologists. It is not revealed by the methods of staining, or indeed the amount of magnification which suffices for diagnostic purposes, and its study has the double disadvantage of requiring special skill and leading to no obvious and immediate results of practical clinical importance. Nevertheless, much time has been devoted to it by Continental observers, and M. Duclaux, in an excellent summary of our present state of knowledge, in a recent number of the Annales de l'Institut Pasteur, refers to a formidable list of forty memoirs bearing upon it.

The opinions expressed show a good many discrepancies, mainly arising from a common cause. Differences of structure in normal bacilli are hard to detect, for the whole protoplasm appears homogeneous; it is therefore necessary to study them either when they have become old and are commencing to disintegrate or with the aid of coloring reagents. The question then arises as to how far the appearances then presented may be taken as indications of the normal structure. The plasma of the bacteria is a gelatinous substance, readily coagulating with the aid of heat or reagents. This has been shown by Butschli, who has actually succeeded in squeezing out this gelatinous material from its envelope. The ease with which the jelly coagulates under different circumstances is one of the main sources of difficulty in its differentiation. One set of observers, among whom A. Fischer and Migula are conspicuous, regards a bacillus as consisting of a capsular membrane containing a mass of protoplasm with a central vacuole, but no nucleus. The vacuole, however, depends too much upon the viscosity of the protoplasm, and, therefore, upon external conditions, to have, in Duclaux's opinion, the importance assigned to it by them. Migula, in fact, considers that the division of a bacterium is preceded by binary fission of the vacuole. Butschli, on the other hand, has studied bacteria and larger, but almost as lowly, fungi, the cyanophyces, by faintly coloring them with acid haematoxylin. He distinguishes a bacterium into three parts, a membrane which does not take the stain at all, a faintly staining peripheral tone, and the much discussed deeply staining central body.

Butschli considers this central body to be, if not a nucleus, at least allied to one in its nature. He has twice, in the case of Beggiatoa, been enabled to detect karyokinesis in it. No difficulty is found in accepting this view as regards the cyanophyces, in which, although large, the central body does not entirely preponderate; but in the smaller bacteria it is found to occupy the whole membrane, the protoplasm being reduced to a mere semilunar thread at each end. This assumption that a bacterium consists practically entirely of a nucleus, with the nutritive protoplasm reduced to a minimum, has not been generally accepted by bacteriologists. Metchnikoff has well compared it to the condition in embryonic cells and in myeloplaxes—that is, where nutritive activity is greatest. Duclaux suggests that protoplasm is, so to speak, the kitchen for the nucleus, which, when in a very active state, can take in its food raw. It will possibly be found that when storage of starch, etc., takes place in a bacterium, protoplasm may be developed around the nucleus as a "tissue of reserve."

Another most interesting question is as to the histology of spore formation. Babes was the first to demonstrate in a number of bacteria, and particularly in that of diphtheria, minute particles taking a violet or reddish stain with methylene blue, and so standing out in sharp contrast to the blue ground.

They were most numerous at the center and extremities of the rod, as if associated with division and growth. He gave them the non-committal name of "metachromatic granules."

Butschli has described them as mainly occurring in the thin protoplasmic layer already mentioned. Certain of them appear to take part in the formation of spores, and here, again, a difference of opinion has arisen.

Ernst described "sporogenic granules" staining with hot, but not boiling, methylene blue, as appearing in certain bacilli under conditions favorable to spore formation, and running together in places to give rise to spores. But Bunge pointed out that these granules were present in some bacilli which did not form spores, and absent in typical spore-bearing forms such as the anthrax bacillus; and farther, that, unlike spores, they did not resist boiling water. He himself describes granules staining less easily than those of Ernst, which appears to fulfill these conditions. They require treatment with an oxidizing agent before they are capable of taking the ordinary stains.

In the anthrax bacillus three or four rounded granules can be seen, which eventually fuse into an oval spore. These granules withstand the action of boiling water, and in this respect and the difficulty with which they are stained agree throughout with the spores themselves. This would seem to show that the difficulty of staining the latter is due to a quality of the material of which they are composed, and not to their being enveloped in an impermeable membrane.

One final point remains for solution—to bring the conclusions of Butschli and of Bunge into harmony it must be shown, as Duclaux points out, that the granules of the latter are formed by the "central body" of the former. This is an important thesis for future observation.—British Medical Journal, London.

THE SALZBURG FESTIVAL.

For hundreds of years the traditional fair with the accompanying popular amusements was held at the Linzer Gate of the old town of Salzburg. The fair has been abolished on account of a complete change in commercial conditions in this region, but the amusements have survived and have been made a festival of the people. Much of the old Dultplatz has been built upon, so that there is not room there now for this fete and it has been removed to Franz-Joseph's Park, a large and beautiful new park near the city.

The historical character which has been given to the festival is a sign of the times, for the study of the customs and habits of the people has become fashionable; the nearer the railroads and the telegraph bring us to one another, the more do we seek to restore and preserve the old customs. This same object was kept in view in arranging the Salzburg festival, the chief attractions of which were a procession of the "Berchten" (fairies or witches of South German legends), a great wrestling match, and a procession in peasant's dress, with valuable prizes for the finest costumes.

The giant Samson and the two dwarfs were brought to the fete from Tamsweg, a little place in Longau. Our illustration shows the strange figure of the giant, which plays such an important part in this little place on Corpus Christi day. As long as can be remembered there has been a procession after the church ceremony, which some declare to be a remnant of a heathen summer festival, while others say it corresponds with the "Maigrafenfahrt." But the parade figure of Samson seems to have survived from the Corpus Christi processions of the last century, of which old historians give a very full account. Then all the heroes of the Bible appeared, even Christ and his disciples being represented.

Samson is represented with a helmet, armor and a sword. A strong man carries the figure on his shoulders, finding a place to look out between the leather straps that form a part of the garment, and the two dwarfs walk near; music precedes them and innumerable followers take a lively interest in the spectacle. We are indebted to the Illustrirte Zeitung for the cut and the interesting details.

THE TAMSWEG SAMSON IN THE PROCESSION AT THE SALZBURG FESTIVAL.

FOREMOST IN LETTER WRITING.

There are 200,000 post offices in all the countries of the world enjoying organized facilities of correspondence, and of this number 70,000 are in the United States, says the New York Sun. In respect of the number of letters and postal cards written and received, the revenue and disbursements of the department, the extent, promptness and accuracy of letter delivery, as well as in the number of post offices, the United States stands at the head of all other nations, Germany following second, Great Britain third, and Austria, among other European nations, fourth. The United States sell in a year 2,000,000,000 two-cent stamps, which is equivalent to 1,000,000,000 letters sent through the mails in a year. In addition to this, the United States sell in a year 600,000,000 one cent stamps, some of which are used for letters, though a larger number for newspaper and circular postage, 12,000,000 three cent stamps, 20,000,000 four cent stamps, and 30,000,000 five cent stamps, mostly used for letters sent from this country for foreign delivery. More than 1,000,000,000 letters a year, therefore, paying full postage, and exclusive of postal cards, are written in the United States.

The business of the German and of the English post office department is less than half as large. The postal card system in Germany is in much more general use than in England, and it is for this reason, perhaps, that Germany keeps ahead of England in respect of the amount of correspondence done. The number of post offices in Great Britain, by the last official statement, made on January 1, 1897, was 20,275, exclusive of what is called in England "the road and pillar letter box." There are 150,000 employes of the post office department in Great Britain, of whom 6,500 are women and girls. The number of post office employes in Germany, where telegraphic communication is a part of the post office system, is 125,000. The number of letters handled by the Austrian post office department in a year is 730,000,000, and of these two-thirds are handled in that portion of the ampire which comes under the designation of Austria, and one third only is handled in the portion officially known as Hungary. The Germans, in Austria as well as in Germany, are great letter writers, and in those cities of the United States in which the German population is numerous more letters are written in a year proportionally than in cities in which the German population is small.

The Italian post office handles 350,000,000 letters a year, the post office department of Spain 130,000,000, of Canada 100,000,000, of Holland 100,000,000, of Belgium 125,000,000, and of Russia 200,000,000, a considerable proportion of which is carried on what are called "the mail coach roads," upon which service the imperial government maintains 30,000 horses. In France the number of letters handled by the post office department is about 700,000,000 in a year, and the receipts of the department are about $35,000,000, or one-half of those of the United States. The French government, however, does a considerable express business, handling more than 40,000,000 parcels, at the rate of one to each inhabitant of the country in each year. The expenditures in the post office department in the United States exceed the receipts by from $8,000,000 to $10,000,000 in an ordinary year. When times are bad, there is less corresponding done.

CONCERNING PUMICE STONE.

An interesting report on the pumice stone industry in the Lipari Islands has been furnished to the British Foreign Office by Mr. Norman Douglass. Pumice occurs on most shores of the Tyrrhenian Sea and elsewhere, but that of commerce is at present almost exclusively obtained from the island of Lipari. It is a trachytic lava, rendered light and scoriaceous by the escape of gases, and every gradation can be traced, from this condition to the heavy vitreous matter of similar composition known as obsidian. Good pumice contains: Silica, 73·70 per cent.; alumina, 12·27 per cent.; potash, 4·73 per cent.; soda, 4·52 per cent.; oxide of iron, 2·31 per cent.; water, lime, etc., 2·47 per cent.

Most of the volcanoes of Lipari have ejected pumaceous rocks at some period or other, but the best stone is all the product of Monte Chirica, with its accessory craters, Monte Pelato and Forgia Vecchia. The district containing the deposits lies in the northeast of the island, and covers an area of about three square miles. The mineral is excavated in various parts of it: in the plateau of Castagna, on the sides of Monte Chirica and Monte Pelato, at Perea, near the seashore of Acqua Calda, and at one or two isolated points. To this end tunnels or galleries are dug into the layers of denuded lapilli and ashes that have gradually covered the pumice. The mineral is sometimes found near the surface, at other times under a layer of white tufa. Digging is not difficult. The tunnels are lighted at intervals by small terra-cotta lamps of antique form, and are so narrow that two men can barely pass. The deficiency of air is soon felt. Sometimes, when a stratum of pumice has been reached, cross cuts are run to gain a larger supply of pumice out of the soft material in which it lies embedded. It is often a matter of

speculation how soon pumice will be reached, so that many tunnels are abandoned while others are worked for long periods. The output may be large one day and almost exhausted the next, or the quality of the stone may change. It has been observed that certain localities produce certain qualities; thus, some of the best pumice comes from Acqua Calda and Monte Pelato, while the inferior variety, known as "alessandrina," is found at Castagna. The number of tunnels actually in working has been estimated at 250, but they vary greatly in size. The number of workmen also fluctuates according to their personal requirements and the season of the year, but has been estimated at about 1,000, of whom 600 are miners.

Pumice is brought to the surface in large blocks or in baskets, and is carried to the village of Canneto by hand or to the seashore, to be taken there in boats. About one-fourth subsequently reaches Lipari by sea. It is there generally stored in the sheds of the merchants, and unless they are in a hurry to dispose of their stock, it is allowed a month to get thoroughly dry. This reduces the weight and shows the quality. After that, large blocks weighing 15 pounds and upward are allowed to crumble according to their cleavage into so-called "biscotti," and all the pumice is then assorted according to its size into (1) large ("grosse," lumps down to the size of a fist); (2) medium ("correnti"); and (3) small ("pezzame," from two inches downwards). The quality is primarily a matter of texture. As pumice is used for polishing purposes, an essential condition is homogeneity of structure and freedom from included crystals. The stone must be neither too brittle nor too hard, and it is in these respects that the Lipari pumice surpasses that of other volcanic regions. After it has been divided according to its size, the large stones ("grosse") are again sorted into three superior qualities called "fiore," "quasi fiore" and "mordente." These are never filed.

After they have been selected, the remainder of the "grosse" are filed by hand, in order to remove asperities of surface and to see whether the stone is not too friable for use. They are then reclassed into first, second and third ("blanche," "dubbiose" and "nere"). Large pieces of inferior pumice, known as "rotonde," are never trimmed. Besides this, there is an entirely different variety called "alessandrina," which is cut with hatchets into brick-shaped pieces and used for smoothing oil cloth, and a heavy dark stone, "bastardone" (always trimmed), as well as many less important varieties. The "correnti," commercially termed "sorts," contain all varieties, and are generally exported as they are; the "pezzame" is usually, but not always, ground to a powder of more than ten different degrees of fineness, according to the work for which it is required.

So extensive are the deposits that the supply is practically inexhaustible. The pumice washed up by the sea is hardly ever collected nowadays. The number of tunnels could be increased indefinitely, and if they were worked on a larger and more systematic scale, the output would probably be trebled. Thus the superior material which is now obtained, not without danger to life, by running tunnels into the precipitous internal crater wall of Monte Pelato, could be reached by longer tunneling from the outside, where there are only a few caves at present. The only menace to the pumice industry lies in the introduction of artificial polishing materials.

THE QUEEN'S HINDOSTANI TUTOR.

THE Munshi Hafiz Abdul Karim, C. I. E., who teaches the Queen Hindostani, came to Windsor in 1887. He was then only twenty-three. He soon began giving lessons in Hindostani to the Queen, who now not only speaks that language fluently, but can write it with more than average correctness in the Persian character. Frogmore Cottage has been assigned to Hafiz Abdul Karim as a residence, and he has been joined there by his wife and his father. Abdul Karim is the second son of Khan Bahadur Dr. Hajee Mohammed Wazirad-din, first class hospital assistant in the Indian medical department. He was for some time in the service of the Nawab Jadla, as Assistant Wakil to the West Malwa Political Agency at Agra. In 1886 he became an Indian government clerk. In the following year he was appointed Munshi and Indian clerk to the Queen, and in 1892 became Indian Secretary to Her Majesty. We are indebted to the London Graphic for the cut and particulars.

THE QUEEN'S LIFE IN THE HIGHLANDS—HER MAJESTY RECEIVING A LESSON IN HINDOSTANI FROM THE MUNSHI HAFIZ ABDUL KARIM, C.I.E.

TECHNOLOGY AT THE TENNESSEE CENTENNIAL.

By MARCUS BENJAMIN, Ph.D., Member of the Jury of Awards.

THE people of the great commonwealth of Tennessee have celebrated the one hundredth anniversary of the admission of their State into the Union by an exposition in the city of Nashville, at which the industrial products of the world were exhibited. As a great object lesson, the Exposition was emphatically a great success, for it afforded a splendid opportunity, to those who were wise enough to visit it, of examining the rich natural resources of the surrounding territory, systematically displayed, as well as many of the manufactured products derived from these resources.

Conspicuous among the exhibits that told a story as if written by nature itself were those of the Southern and of the Nashville, Chattanooga and St. Louis Railways in the Terminal building. The former exhibit—that of the Southern Railway—had three conspicuous features. Agriculture, being the basis of all industries, was given the central place in the hall, while the products of forestry and mining were arranged on either side. The agricultural display consisted of a great variety of farm and garden products and showed the crops that flourish in the most productive regions of the Southern States, as well as the richness of the soil, the favorable climate and the labors of the people. There were specimens of oats, corn and rye from every State and rice from the Carolinas. During 1896 101,024,547 bushels of grain were raised in the eight States through which the Southern Railway passes. There were glass cases filled with silken yellow-leaved tobacco of Virginia and North Carolina, and still others in which the heavy, dark tobacco of Kentucky, Tennessee and elsewhere was displayed. Remarkable exhibits of fruits and vegetables were made, together with samples of the Muscadine and the more famous Scuppernong wine; indeed, it is claimed by some that the vineyard regions of the Southland are now able to produce wines "that vie with those of the valley of the Rhine and the sunny slopes of France."

Of cotton and its products more must be said. Raw cotton from the States of Mississippi, Tennessee, Alabama, Georgia, North and South Carolina, was shown, and from these States 4,758,394 bales were produced in 1896. A sign with the words "The Southern Railway cities and towns have erected a million spindles in two years" was conspicuously displayed, and there seemed little doubt as to the verity of the statement, for there were samples of yarns, hosiery, cassimeres, cheviots, stripes, plaids, shirting, suitings, cottonades, ticking, fine bleached cloth, doilies, tray covers, towels, napkins, goods for aprons, goods for either drawn work or embroidery and goods for all kinds of underwear, as well as all kinds of thread. There are now in the States of Kentucky, Tennessee, Mississippi, Alabama, Georgia, the Carolinas and Virginia 434 cotton mills, with 3,451,-631 spindles and 90,108 looms, besides 72 knitting mills. Of these, 249 cotton mills and 37 knitting mills are on the line of the Southern Railway. These mills have 2,-304,367 spindles and 66,561 looms, being two-thirds of all the looms and spindles in operation in the South east of the Mississippi. The products of the woolen mills along the line of this railroad were represented by a great variety of fine merino doeskins, jeans, diagonal cloth and many samples of various "all wool" cloths. There are some 88 woolen mills distributed among the States as follows: Alabama, 2; Georgia, 5; Kentucky, 18; Mississippi, 1; North Carolina, 13; Tennessee, 25; and Louisiana, 24. Of the total number given, about 15 are also cotton or knitting mills.

The lumber interests of the South are now one of its most important industries, and an interesting feature of this exhibit was specimens of the native woods, many of which were planed and varnished so as to show fully

the beauty of the natural grain. The manufactured articles on exhibition included ax and hammer handles, spokes, spigots and furniture.

Of considerable interest was the mineral exhibit. One side of the hall was wainscoted with slabs of marble. A great variety of the famous marbles of East Tennessee and Georgia was shown, and it will be recollected that the new Congressional Library building in Washington contains much of this beautiful mineral from these localities. Several interesting fancy marbles were conspicuous, notably the leparlite from near Charlotte, N. C., and a mottled gray variety containing fossil shells from Varnells, Ga. Blocks of granite from Richmond, Va., and Winston, N. C., gneiss from Jackson, Ga., and a stationary wash tub of soapstone from North Garden, Va., as well as slates and limestones of excellent qualities, were shown.

Of the metallic minerals, the display of iron ores was naturally a fine one, and it must be remembered that Alabama is now the third State in the Union in mining iron ore and the fourth in the manufacture of pig iron. Gold ores from mines in the Carolinas, in Virginia, in Georgia, and in Alabama were shown, together with casts of important nuggets; of these, one from the Reed mine in Cabarrus County, N. C., found April 10, 1896, weighed 22 pounds. Tin, nickel, and zinc ores were also shown.

The display of kaolin and clays was not only fine, but it is proper to add some of the very best deposits of kaolin in the United States are to be found in the Carolinas.

As yet no great potteries have been established in the South, but specimens of manufactured wares made in East Liverpool and in Trenton from Southern clays were shown. Of passing interest was the black pottery made by the Cherokee Indians in North Carolina. That the great demand for mineral waters is not ignored in the South was apparent by the many varieties shown as coming from points along the line of the railway.

The exhibit of the Nashville, Chattanooga & St. Louis Railway was by no means inferior to that of the Southern Railway, but as the territory covered by this road is not so great, it failed to produce so effective an impression of the resources of the South as its greater rival.

Of agricultural products, more than one hundred and fifty specimens of crops, garden vegetables and textile grasses, all labeled, were shown. A special feature of this exhibit was the showing of the variety of products that could be obtained from single localities, and there were exhibited seventy-three separate and distinct crops taken from a single farm of twenty-five acres. The forestry exhibit was a splendid exhibition of the woods of Tennessee. Five hundred sections of trees so prepared as to show the grain of the wood were to be seen. From one farm in Montgomery County forty-five single specimens of hardwood were procured. In all one hundred and seventeen specimens of wood from Tennessee were shown by the Nashville, Chattanooga & St. Louis Railway.

The largest hardwood lumber market in the world is Nashville, and the value of the annual output of lumber, including staves, spokes, hubs and bent work, is $9,078,-686. Specimens of nearly every mineral of economic value to be found in Tennessee were shown, as well as the varieties of iron ore, asbestos, tripoli, corundum, bauxite, manganese, coal, and several varieties of phosphate of lime, also hydraulic cement rock and potter's clay, marbles, both white and variegated, building stone of fine polishing qualities, both sandstones and limestones, grindstone grits, lithographic stones, and others of value.

An interesting exhibit of yellow tobacco was shown, and it is claimed that the success that has attended the cultivation of this variety of tobacco will lead to the developing of much land in Tennessee hitherto believed to be sterile.

Adjacent to the Agricultural building were several fields containing cotton and tobacco plants showing the methods of cultivation, and in the building itself the curing process was practically shown.

Of perhaps more distinct value in technology was the exhibit in the Agricultural building of the German Kali Works. Of course not so imposing an array of the salts was shown as was the case in Chicago, but "comparisons are odious," and it is sufficient to say that the kainit and other minerals so extensively used for fertilizing purposes were artistically displayed. Naturally in this building the exhibits in which we have most interest were articles used in the preparation of food, and of this character were the different varieties of gelatine on exhibition. Of similar nature was the "cotosuet," composed of prime cottonseed oil and used as a shortening. The beef extract, both in the liquid and solid forms, was a conspicuous feature of the exhibits made by the large packing firms of Chicago. Also in the Agricultural building was the unique exhibit from far-away Utah. Conspicuous among the products offered for inspection from the fertile valley of Salt Lake was the sugar from the beet sugar works at Lehi, where each year nearly 5,000,000 pounds of sugar are made from beets grown in the vicinity, and for which the farmers receive $150,000. As the bitter accompanies the sweet, so to counterbalance the sugar, Utah exhibited the salt produced by three companies whose works are in the immediate vicinity of Salt Lake City. Prof. Talmadge, of the University of Utah, describes the method of producing the salt as follows:

"The water is lifted by the aid of centrifugal pumps to a height of 14 feet above the lake surface; it is then conveyed through flumes to the evaporating ponds, which are from one to two miles inland. The largest of these companies is the Intermountain Salt Company, which claims to have 974 acres in ponds. Part of this constitutes a storage basin. Pumping is begun early in March and is continued about 150 days. The pumps have a capacity of 14,000 gallons a minute and run ten hours a day. By the time the ponds are filled the evaporating season is well advanced, and about the same supply is needed to keep the brine at the proper level. About one-tenth of the amount of brine carried to the ponds is returned to the lake after the deposition of the crystals. The salt deposit, as reported, averages 6 inches depth and yields 900 tons to the acre, or at the rate of 150 tons an inch depth to the acre. The pond floor consists of saline mud which seems to be practically watertight. When the salt harvest begins, usually in August, movable railway tracks are run into the ponds and the crop is gathered into hand cars. It is then heaped in large symmetrically constructed piles and as required is conveyed to the works. With so simple a process of production, the manufacturers are able to offer the coarse salt at from seventy-five cents to a dollar a ton. The refining process comprises the following operations: 1. The crude salt is run through a drying cylinder. 2. The dried coarse salt is subjected to fan action, whereby the finer powder is removed; this takes out most of the efflorescent sodium sulphate, which has assumed the condition of dust during the drying process. 3. The granular salt is then ground to varying degrees of fineness and is offered for sale as dairy salt, table salt, etc. The lake salt so prepared is of a high grade of purity; indeed, it may challenge comparison with commercial salt from any other source."

The mineral exhibit from the new State was of interest and the rich gold ores from the Mercur and Golden Gate mines testified to the great value of these deposits, which are much nearer at hand than those of the Klondike. The present output from the Mercur mine is said to be 200 tons a day, with an average value of thirteen dollars a ton. "Conservative estimates place the amount of ore in sight at three million dollars and yet the door of the mine has just begun to swing upon its hinges." And Utah is also rich in silver and iron ores, and then its hydrocarbon minerals, including gilsonite, elaterite and ozerkerite, must not be forgotten. Well may one wonder as to "what shall the harvest be?" when the resources of Utah are developed.

By far the most important exhibits were in the Commerce building, as the edifice was called in which articles belonging to the departments of manufactures and liberal arts were housed. Unfortunately for this paper, however, there were comparatively few exhibits that were of conspicuous interest. In the way of heating and illumination there were several fine displays of stoves and furnaces. The stoves came chiefly from the large factories in Detroit, and several forms of cooking stoves were shown with arrangements for both coal and gas, thus providing a means by which during the colder months the heavier fuel was to be used, while in summer the more convenient gas was to be employed. Many of the designs were elaborate, and one stove was shown in which the iron had been entirely replaced by aluminum. For this variety the claims were naturally cleanliness and lightness. Several furnaces for heating were on exhibition, and the chief characteristic to be noted in these was the passage of the smoke over the bed of the furnace in such a fashion as to consume the carbon particles. They were also built so that they could be cleaned rapidly and without difficulty. An exceptionally fine display of lamps was made by the well-known Rochester Lamp Company.

The costliest exhibit in the building was that of an elaborately carved altar, valued at $8,000, on either side of which were two cathedral windows containing the handsomest stained glass ever exhibited in the South. They were of American manufacture. On the floor were tiles from Zanesville, Ohio, of new and pleasing design and specially adapted for flooring. These were one of the few novelties that were to be seen in the Exposition. On the eastern aisle was an exhibition of some exceedingly well made tiles from a Southern factory near Asheville, which has recently been started and from which it is said that the tile work in Mr. George Vanderbilt's home at Biltmore is made; indeed, the clay from which the tiles were made is obtained on the estate itself. These were free from crazing and the glazing in consequence was very uniform. Some interesting specimens of the so-called Tiffany architectural brick were in the immediate vicinity and were of excellent manufacture.

Also in the same aisle was an exhibit by the Dupont Powder Company. It consisted of specimens, neatly installed and well labeled, of the crude materials used in the manufacture of powder, that is, twigs of wood and the resulting charcoal, together with sulphur and saltpeter. Then followed the various forms of shooting and blasting powders, as well as specimens of smokeless powder. There were no exhibits from any of the great drug houses of the country, although one enterprising firm from New York exhibited its emulsion of hypophosphites of soda and lime, showing the crude materials and also an upright tube filled with the emulsion, to demonstrate that it did not separate on standing. During the life of the Exposition this tube, fully six feet long, stood, sentinel-like, in front of the exhibit, and even at the last it was quite impossible to see any evidence of separation. Adjacent to this was shown by a Philadelphia firm a most palatable mixture of cod liver oil and port wine, in which the taste of the oil was completely disguised and in fact made so agreeable that a physician's prescription of such a medicine would be gratefully received by even a well person.

There were five exhibits of beers made by firms in Milwaukee, Cincinnati, Louisville and Nashville, and although samples were not given away, still the attractive manner in which the beer was displayed caused many to admire the installment. One exhibit in particular consisted of an enormous beer bottle, composed entirely of smaller bottles.

Flavoring extracts, perfumes and soaps were exhibited by several firms. One of the Nashville wholesale druggists had excellent varieties of perfumery made from crushed violets and crushed roses, that were unusually strong and persistent in their odor. Flavoring extracts made from the fruits themselves, together with specimens of fruit in the menstruum, were among the attractive exhibits of this variety. The peach and strawberry extracts were uncommonly strong and appetizing. Another firm in this line had an exhibition of "Standard Color Pastes" which were free from all harmful and injurious ingredients and were recommended for use in giving "color touches to food materials." It is claimed that for the use of coloring lunch tables there is nothing like them. Such effects as are needed in pink, green, or violet lunches are readily obtained by these harmless preparations. Nine rich shades of these pastes were shown and they are soluble in milk, water or spirit. They are fast to light and unchanged by fruit acids. This same firm exhibited an eau de cologne that closely resembled the celebrated brand made by Farina, "opposite the Cathedral," in musty and dirty old Cologne.

In the foreign section of the Commerce building the exhibits in technology naturally ran to objects of art. The most important of these was pottery. The exhibit of the Royal Copenhagen wares was indeed fine and included not only vases and plaques, but also several of the interesting reproductions of animal forms for which that factory is noted. One or two porcelain fish and a lobster on a piece of brick were characteristic specimens. Adjoining the pottery exhibit just mentioned was that of the Widow Ipsen's famous terra cotta wares. Statuettes and vases, especially those imitating in their general appearance and decoration the beautiful forms of ancient Greece, were notable. It is such exhibits as these two that have a great value in showing our native manufacturers their deficiencies. Italy had several exhibits of her characteristic majolica wares, and in one case the son of the potter himself accompanied the exhibit; and of more than passing interest is the fact that the boy, finding a satisfactory clay on the grounds, had reproduced several of the favorite patterns of his father's ware in Nashville clay. These were baked and then crudely decorated with paint, after which they were sold as souvenirs. The name of the lad was G. Bonato. Small statuettes with clever reproductions of native costumes, modeled by hand in clay and then baked, were likewise shown in the Italian section. Many of these figures were colored by hand. They were conspicuous among the artistic objects of the Exposition, and were worthy of high praise.

Sweden also sent specimens of her ceramic wares from the well known potteries of Hoganas and Rörstrand. Indeed, the American potters deserve the severest censure for making no exhibits, and were put to shame by the potteries from over the seas.

A new variety of iridescent glass, suggesting in form and appearance specimens dug up in Cyprus and elsewhere, were exhibited by a Danish firm. The brilliant and gaudy varieties of Hungarian and Bohemian glass were there in all their beauty and called forth pleasant memories of the Austrian section in Chicago. There was silver filigree work from Italy and an English exhibit of solid silverware. But nowhere in the Exposition was the Tiffany glass shown, and nowhere were the splendid works of our American silversmiths to be seen. Then there were laces from Belgium and laces from Russia. Also samovars and furs from the land of the White Czar, but not even so much as the head of a buffalo from an American dealer in furs.

A novelty from England was the tabloids of compressed tea, which were recommended as being "convenient, portable, economical, and reliable." One or two tabloids placed in a cup, which must then be filled with fresh boiling water, stirred and allowed to stand for a minute or two for the purpose of allowing the sediment to settle, yield a comfortable cup of tea. An interesting varnish enamel called "Psycroganome" was exhibited by a firm from Italy. This varnish, which comes in some twenty colors, is applied with a brush and forms on drying a hard enamel which resists the action of hot water, steam, and even acid solutions containing as high as two per cent. of sulphuric, hydrochloric, or nitric acid. It has been largely used abroad in hospitals, where in consequence of the ease with which it can be washed, and as it is not affected by disinfectants, it has proved of great value from a hygienic point of view. It has been used by the Italian government in large quantities in the interior of several of their recently constructed men-of-war.

In the remaining buildings there were but few exhibits that come within the scope of this article. Naturally in the Woman's building were many interesting specimens of ceramic wares painted by American women, but for the most part they were on foreign bodies. An exception to these were the beautiful vases and bowls exhibited by Miss Louise McLaughlin, of Cincinnati, who was associated with Mrs. Bellamy-Storer in the Pottery Club that led to the founding of the Rookwood Pottery.

In Machinery Hall was a most interesting exhibit—the Laflin & Rand Powder Company. Not only were samples of charcoal, sulphur and saltpeter shown, but also the various grades of saltpeter made by them. In addition, the different varieties of gunpowder, as well as mining, blasting and smokeless powders, were shown. This exhibit was especially attractive for the reason that it included a model of a powder mill worked by electricity. Although the actual manipulation was not shown, still the machinery in miniature was there and in actual operation.

The Mining building contained much that was of interest in the way of ores, minerals and their products, including a number of clays with the resulting ceramic wares. One attractive exhibit was specially notable. It consisted of a small structure or building made of fine pressed and ornamented brick erected by a firm in Nashville, roofed over with interlocking clay tiles from Chicago, similar to those used on the German government building at the World's Fair.

Doubtless in this necessarily brief and hurried summary of what appealed to the writer as being of interest in the department of technology there is much that is missing, but if there is any lesson to be derived from the exhibits at the Nashville Exposition it is that there is an individuality in the goods made abroad and which it is sad to say is lacking in our home manufactures. The United States, which should lead in every kind of manufactures, as it does in some few cases, will never create a distinctive class of goods until they cease to be imitators of foreign wares. May the time soon come when all kinds of things made in this country shall be as clearly distinctive of the United States as is the cotton gin invented by Whitney, the sewing machine of Howe, the telegraph of Henry, or the telephone of Bell.

A press dispatch says: "The discovery of petroleum is reported from Alaska. Some gold prospectors several months ago ran across what seemed to be a lake of oil. It was fed by innumerable springs, and the surrounding mountains were full of coal. They brought samples of the oil to Seattle, and tests proved it to be of as high grade as any ever taken out of Pennsylvania wells. A local company was formed and experts sent up. They have returned on the steamer Topeka, and their report has more than borne out the first reports. It is said there is enough oil and coal in the discovery to supply the world. It is close to the ocean, and the experts say that the oil oozes out into the salt water. It is said that the Standard Oil Company has already made an offer for the property. The owners have filed claims on 8,000 acres."

ENGINEERING NOTES.

The dust collected from the smoke of some Liege furnaces, burning coal raised from the neighboring mines, produces, when dissolved in hydrochloric acid, a solution from which considerable quantities of arsenic and several other metallic salts may be precipitated.

Licata, on the south coast of Sicily, at the mouth of the Salso, the ancient Himera, is about to build a large commercial harbor in the expectation of drawing the trade from the East that now goes to Naples and Brindisi, as it is on the direct route from Port Said to Gibraltar.

The weight of a given bulk of cast aluminum being known, the relative weight of similar castings of the common metals can be roughly found by multiplying by 2·9 for soft steel or iron; by 3·12 for copper; by 3·41 for nickel; for silver, 4·38; for lead, 4·4; for gold, 7·5; and platinum, 8·35.

Burma grows a hard wood called Pyinkadoe which, the British have found, makes excellent railroad sleepers. The wily Burmese, however, who sell the wood, having discovered that the British engineers know little about it, have taken to dyeing cheap wood a reddish color and palming it off for Pyinkadoe.

The total tonnage of the fleet of the Hamburg-American line is 290,000 tons, excluding the river boats which run to Heligoland and Norderney. This total places the company in the first place of all steamship companies, the second being the North German Lloyd, with a total tonnage of 265,000 tons, next the Peninsular & Oriental Company with 240,000 tons, and fourth the Messageries Maritimes with 220,000 tons.—Uhland's Wochenschrift.

When some thirty years ago the Japanese Steamship Company (the Mitsu Bishi Company) was founded, it had a fleet of some half a dozen ships. In 1870 it commanded over six sailing vessels and thirty-six steamers. In 1885 another company was incorporated with it, and at the present time the company possesses sixty-seven steamers, with a total tonnage of 133,600 tons. Orders have been given for twelve new steamers of 5,000 tons each, and the purchase of six more is being considered.—Stahl und Eisen.

There are thirty shields at work upon the construction of the Central London Railway, and over three thousand men engaged. The company has just completed half the tunneling process and put the two circular tubes to shape, which are to be run side by side for about five miles. Considerable trouble has been experienced at the Bank station—which is to be the City terminus, and not Liverpool street, as at first intended—owing to the City sewage pipes being in such close proximity. According to The Railway News, Christmas of next year is the earliest possible date of opening.

The right of working the Elba iron ore mines has been accorded to M. Tonietti, son of the previous concessionaire, on the basis of a royalty of 7·25f. per ton of ore exported, says The Engineering and Mining Journal. The royalty is a heavy one in comparison with the 4·50f. obtaining in the previous contract. According to the new contract, the annual output must not be less than 100,000 tons nor more than 200,000 tons. The concessionaire must employ a certain number of workmen and must keep the Follonica charcoal furnace in blast. After the exportation of 2,000,000 tons of ore, the royalty will be reduced one-third.

The London Trade Journal says: "The managers of the Saxon state railways are stated to be planning the establishment of a railway museum, which will be located in reserved rooms of the general railway building at Dresden. A vast number of exhibits have already been collected, particularly of models, printed matter and drawings, which partly belong to the very earliest railway period, and which for this reason will probably claim the attention not only of persons conversant with railway affairs, but of the educated public generally. When the opening of the museum will take place is not settled yet; it is only certain that in the first instance the close of the Leipzic Industrial Exhibition will be awaited, because a great portion of the objects to be put into the new museum are at present on exhibition there."

The Alpine-Montangesellschaft, in Austria, says The London Iron and Coal Trades Review, is really a federation of the chief works in Styria and Carinthia, and it has grown in importance and influence since it was founded, nearly twenty years ago, until now it employs 15,732 hands—of whom 417 are women and 507 children—and produced in 1896, 880,000 tons of brown coal, 166,000 tons of iron ore, 252,000 tons of pig and 134,000 tons of half and wholly manufactured iron and steel. Ten works owned by the Gesellschaft produce pig iron, three produce Bessemer steel and four produce open hearth steel. The total output of both descriptions was in metric tons: In 1896, 44,992 tons Bessemer and 121,472 tons open hearth. More than 20 per cent. of the total output of pig is manufactured with charcoal fuel, while brown coal is chiefly used for the remainder.

Painting gas holders by a compressed air spray has recently been tried by the Turner Machine Company, of New York City, with complete success, and it is stated, says Engineering News, with considerable economy over painting by hand. The painting was done on the gas holders of the Equitable Gas Company, of New York, which are located at Fortieth Street and Avenue A. In doing the painting the holders were first lowered and the top and three 2 foot sheets of the sides were painted, working from the ground. The holder was then gradually raised as the painting of the sides progressed. Owing to the necessity of using the tanks for storage, it is stated that the work was frequently interrupted, and there was only one day during which the work progressed steadily. On this day the top and 18 sheets of the sides were painted on a holder 90 by 90 feet and 24 sheets high. The work was carried on from 8:30 A. M. to 5 P. M., and the area painted was between 16,000 and 17,000 square feet. Three men, using two sprays, did the work, at a cost for labor of $6.25, or less than half a cent per square yard. About the same amount of paint was used as would have been the case in painting by hand. A man with a brush can [illegible] on 1,200 to 1,500 square feet per day.

ELECTRICAL NOTES.

Dr. Jameson has taken charge of the construction of the transcontinental telegraph line across Africa from north to south. For the present it will not extend beyond Lake Tanganyika.

The best results hitherto obtained in all attempts to make an electric cell which should consume carbon are those of Bartoli and Papasogli, whose cell consisted of platinum, carbon and caustic soda solution. The voltage obtained by this method was 0·2 to 0·3 volt. Mr. Coehn has made further researches on the same problem, and by a cell which has for its anode carbon, for its cathode lead peroxide, he has obtained as much as 1·06 volts. The great objection to this battery is the high price of lead peroxide, which makes it useless for practical purposes, though as a scientific curiosity his cell has great merits.—Uhland's Wochenschrift.

"The Bibliography of X Ray Literature and Research, 1896-1897," will be published in a few days by the Electrician Printing and Publishing Company, London. The book is edited by Mr. C. E. S. Phillips, who has also contributed an Historical Retrospect, and a chapter on "Practical Hints on Roentgen Ray Work." The same company also issued at the end of October a new work by Messrs. Fisher and Darby, entitled "The Student's Manual of Submarine Cable Testing." The publication of this work is opportune from the fact that the great cable companies now require on the part of their operators and probationers a more general acquaintance with electrical work, and Messrs. Fisher and Darby have written a book which is intended to serve as a manual for young men engaged in the cable service or who may contemplate selecting that career.

The increased use of electric power during recent years has led to a largely increased demand for mica for insulating purposes. But the producers of mica have not found in the electric demand any relief from the state of affairs which was a continual source of loss to them before it began. Large sizes and good shapes of mica such as are required for insulation purposes were always marketable, but the difficulty remained of disposing of the waste or scrap which forms so large a percentage of the output of mica mines and accumulates so rapidly at mica-cutting works. Through the ingenuity of Mr. H. C. Mitchell, of Toronto, this waste mica has now a value, though no doubt a small one as compared with the merchantable sizes. It is being utilized as material from which to manufacture coverings for boilers and steam pipes to lessen the loss of heat by radiation, mica being a good non-conductor of heat as well as of electricity.

Some interesting observations concerning the physiological effects of electric currents have been made by M. Dubois, says The Electrical Engineer. He finds that the effect depends much more upon voltage than upon intensity. With the same voltage, for instance, a fall of the resistance from 270,000 to 72,000 has no effect, at least as far as the minimum of perception is concerned. But a profound effect is produced by the insertion of external resistances, owing to their self-induction. Even the most non-inductive resistances have a marked effect. The inductance of the human body is practically zero, and hence the great difference produced by the slightest internal inductance. But the effect of an external resistance may be compensated by inserting a capacity in the circuit. In one case quoted a capacity of 0·0045 microfarad re-established the physiological effect, which had been canceled by the insertion of a resistance of 600 ohms.

The trial trip of the New York Fourth Avenue underground trolley took place October 31, and was a success. One of the new electric cars left the Thirty-second Street stables about 11 o'clock forenoon, ran to Forty-second Street, then down to Astor Place and Broadway, and back to the stables, making the round trip in thirty-five minutes, which is about schedule time. There followed along behind it, as contrast between what was and what is to be, one of the old stage-like cars of the style of 1850, drawn by two horses, and resurrected for the occasion. The new car was greeted by cheers along the route. It made no stop for passengers, but frequent stops to test its mechanism. W. A. Pearson, electric engineer of the company, acted as motorman, and M. Marks was its conductor. President Vreeland, General Superintendent F. D. Rounds, Chief Engineer F. S. Pearson, General Master Mechanic Thomas Mills, James Regan, general foreman of the Fourth Avenue division, and other officials of the road were passengers. It is expected that the new cars will be running regularly in a very few days.

Starting from the fact, which is obvious even to the unscientific person who has handled a chimney lamp, that gas at a temperature above red heat may emit absolutely no light whatever, it might easily be assumed that the temperature of the glowing residual gas in a Geissler or other vacuum tube was really very high indeed, says The Electrical Engineer. E. Wiedemann and Hittorf, as well as Warburg, have stated cautiously that the temperature of the residual gas when emitting light was probably well below red heat, a conclusion which ought not to be very difficult to arrive at when the small total amount of heat emitted is considered. Mr. R. W. Wood has recently endeavored to settle the matter definitely, and his results have been published in The Physical Review. In order to obtain the different temperatures in different parts of a stratified discharge he used a bolometer, consisting of a loop or spiral of very fine platino-iridium wire. The constant current was used from a 600 cell accumulator battery, and the tube was a Hittorf one. The details of the experiments and the results would occupy too much space to be set out here, but in every case it seems that the rise of temperature as measured in the way indicated is only a matter of from 2 degrees to 10 degrees C., according to the gas used and its pressure. The temperature is lower in the dark spaces than in the bright ones, so that it is clear that a part of what was measured was simply "light" measured as "heat." The method is not free from difficulties, but the results so far as they go support the contention that if it were only possible to use it a vacuum tube method would convert a greater proportion of electrical energy into light than any other means of electric lighting. Unfortunately there seems little or no likelihood of its being or becoming possible.

MISCELLANEOUS NOTES.

Menelek, of Abyssinia, is running Kaiser Wilhelm close in the variety of his accomplishments. He showed the French envoy, M. Lagarde, the plans he had drawn with his own hand for his new palace at Addis Adaba. When the first sewing machine he had seen came to him out of order, the Negus looked it over, found out what was wrong, and repaired it himself.

The writer of an article in a recent issue of the Marine Rundschau has laid before his readers a carefully thought out estimate of the fighting values of the various fleets expressed in terms of units. After dealing with the fleets of England, France, Russia, Germany, Italy, the United States, and Japan, the conclusion is arrived at that there is only one sea power of the first rank, namely, England. Expressed in units the author of the article estimates the English fleet at 1,091, the French at 466, the Russian at 290, the American at 195, and the Japanese at 170.

Admiral Makaroff, who has just returned from his expedition, expresses his opinion that it is possible to travel to Siberia by water through the Arctic Sea. That fact has been demonstrated; but what the admiral means is that it will be found possible to make the voyage every year. In some years the Kara Sea is completely blocked with ice, and it is suggested that pilot boats fitted with ice plows should be provided as an escort for the merchant steamers. Several vessels of the kind, called "ice breakers," have worked very successfully in America and elsewhere.

Mr. Ferrey, of London, England, has devised a simple improvement on cylinders, such as are used for storing compressed oxygen, carbon dioxide, etc. Instead of making them of smooth surface, as usual, he provides them externally with a screw thread. The result of this is twofold: A sudden stress merely produces an elongation of the cylinder, the thread tending to assume an axial position, while a slow increase of pressure above the maximum permissible, instead of resulting in an explosion, causes a slow breaking only along the grooves of the thread.—Uhland's Wochenschrift.

Progress in iron manufacture is exemplified in the sizes of the largest ingot and single piece of metal shown at the 1851 exhibition compared with the corresponding products of to-day. Forty-six years ago an ingot weighing 1 ton, and a forged bar weighing 7 cwt., were the best things forthcoming; ingots of 70 tons weight are now quite ordinary affairs at Messrs. Vickers' works in Sheffield, where also guns of 100 tons can be turned out. Their tools include seven planing machines that will each work up a surface 10 feet 6 inches square, and two others for dealing with armor plates 18 feet by 12 feet.

Edmund Carey of Benton was one of the early residents of Wilkes-Barre and was born August 12, 1822, on a farm at the lower end of town, now known as Carey Avenue, which has been named after the family. His father, George Carey, was one of the settlers who had the handling of the first anthracite coal in Wyoming Valley. He helped open a stripping in Pittston Township, now known as Plains Township, in 1815, and in the spring of that year loaded a raft with several others and took it down the Susquehanna to Harrisburg, where they sold the raftload of 40 tons of anthracite for $10. They were discouraged at such remuneration and left the transportation of coal dormant until 1820, when they took another raftload down and failed to find a buyer. They were so discouraged that they dumped their load of black diamonds into the Susquehanna at Harrisburg, and as far as these early pioneer shippers were concerned the opening up of a coal market was ended.—Wilkes Barre (Pa.) Record.

A new process for the artificial ageing of whisky is described in a chemical contemporary, and it is claimed that the process, which has hitherto taken some years to accomplish, can now be effected in as many hours. Briefly, it consists in exposing the largest surfaces of spirit and air to each other by means of a spray, and under the influence of a temperature of about 82° F. The air and spirit only come into contact once, and the low temperature at which the latter is maintained condenses it and prevents the operation resulting in the whisky losing aroma or flavor. There is said to be very little loss of strength. The time of working is four or five hours, according to the size of the plant and the quantity of spirit to be treated. The plant consists of ammonia compressor, condenser, refrigerator and spray vessel, driven by steam. An ingenious inventor, whose name has been closely connected with the production of ozone electrically, claimed, some years ago, to be able to produce adolescence in this popular beverage by submitting it to an ozonizing treatment, but we have not heard of any successful commercial results.

It is now three years and a half since the money bequeathed by Benjamin Franklin to the city of Boston for the benefit of its young workingmen became available under the terms of his will; that is, at the end of 100 years from his decease. The trustees of the fund, which now amounts to nearly $350,000, decided, after a prolonged controversy and much deliberation, and after the matter had been passed on by the courts and State legislature, to devote it to "the purchase of land and erection thereon of the Franklin Trades Schools and to the equipment of the same, under the direction of such department as may, for the time being, be charged by the statutes and ordinances with the duty of erecting and furnishing public buildings in the city of Boston." They paid the money to the city treasurer with this object, but no steps appear to have been taken toward beginning the work. Now it seems that the Franklin Fund is again to be submitted for the courts to adjudicate upon. A press dispatch from Boston says that it has been decided to apply to the Supreme Court for power to compel the city treasurer to pay over to the trustees that part of the fund in his possession, as, in the opinion of City Solicitor Babson, under the peculiar circumstances connected with the fund it is not regarded as safe to pay the money out of the city treasury to the trustees until the matter shall have been passed upon by the Supreme Court. It is unfortunate that so many delays should take place in the progress of the plan, for the establishment of such a trade school as that contemplated by the Franklin Fund trustees would be an immense benefit to Boston

SELECTED FORMULÆ.

Celery Compounds.—

Celery (seed ground)	25	parts.
Coca leaves (ground)	25	"
Black haw (ground)	25	"
Hyoscyamus leaves (ground)	12·5	"
Podophyllum (powdered)	10	"
Orange peel (ground)	6	"
Sugar (granulated)	400	"
Alcohol	150	"
Water, q. s. ad	400	"

Mix the alcohol with 150 parts of water and macerate drugs for 24 hours; pack in percolator and pour on menstruum till 340 parts is obtained; dissolve sugar in it and strain.—Bulletin of Pharmacy.

New and Brilliant Blacking.—A new and brilliant blacking for shoes, which has the advantage, furthermore, of being acid free, is thus described: Boil together for two hours 30 parts of powdered gall apples and 30 parts of rasped logwood in 200 parts of water. Strain off while hot; add 200 parts of sirup and 30 parts of iron sulphate in powder. Boil the liquid until it begins to thicken, and then add 10 parts of ruby shellac in 200 parts of alcohol.—Bulletin of Pharmacy.

Dyeing Leather.—We are placed in possession of the following particulars regarding the dyeing of leather through the courtesy of The Leather Manufacturer, of Boston: In dyeing leather, aniline or coal tar colors are generally used. These dyes, owing to their extremely rapid action on organic substances, such as leather, do not readily adapt themselves to the staining process, because a full brushful of dye liquor would give a much deeper coloration than a half exhausted brush would give. Consequently, to alter and to color leather by the staining process results in a patchy coloration of the skin. In the dyeing operation a zinc shallow trough, 4 to 6 inches deep, is used, into which the dye liquor is put, and to produce the best results the contents of the trough are kept at a uniform temperature by means of a heating apparatus beneath the trough, such as a gas jet or two, which readily allows of the heat being regulated. The skins to be dyed are spread out flat in the dye trough, one at a time, each skin remaining in the dye liquor the time prescribed by the recipe. The best coloration of the skin is produced by using three dye troughs of the same dye liquor, each of different strength, the skin being put in the weakest liquor first, then passed into the second, and from there into the third dye liquor, where it is allowed to remain until its full depth of color is obtained. Very great skill is required in the employment of aniline dyes, as if the heat be too great, or the skins remain too long in the final bath, "bronzing" of the color occurs. The only remedy for this (and that not always effectual) is to sponge the skin with plenty of cold, clean water, directly it is taken out of the final dye bath. The dyed skins are dried and finished as before.

LEATHER BROWN.

Extract of fustic	5	ounces.
Extract of hypernic	1	"
Extract of logwood	½	"
Water	2	gallons.

Boil all these ingredients for 15 minutes, and then dilute with water to make 10 gallons of dye liquor. Use the dye liquor at a temperature of 110° F.

As a Mordant.—Dissolve 3 ounces of white tartar and 1 ounces of alum in 10 gallons of water.

FAST BROWN.

Prepare a dye liquor by dissolving 1½ ounces fast brown in 1 gallon of water, and make a 10 gallon bulk of this. Use at a temperature of 110° F., and employ the same mordanting liquor as in last recipe.

BISMARCK BROWN.

Extract of fustic	4	ounces.
Extract of hypernic	1	"
Extract of logwood	½	"
Water	2	gallons.

Preparation.—Boil all together for 15 minutes.

Method of Dyeing.—First mordant the skins with a mordanting fluid made by dissolving 3 ounces tartar and ½ ounce borax in 10 gallons of water. Then put the skins into the above foundation bath at a temperature of 100° F. Take them out, and then put in 1 ounce of Bismarck brown, dissolved in boiling water. Put the skins in again until colored deep enough, then lift out, drip and dry.—American Druggist.

Toning Lantern Slides.—Th. J. Placzek, of Vienna (Photograph. Corresp.), gives the following directions for toning of collodion transparencies: If pyrogallic acid be used, instead of iron, for development, a pleasing blue black deposit results, that can be easily toned with neutral chloride of gold, chloride of palladium, etc., but the large addition of glacial acetic acid to the developer makes double the exposure necessary as compared with iron development. In consequence of this attempts have been made to tone the grayish-black image of iron developed positives, and the following bath has been found very useful:

Solution potassium chloroplatinite (1:50)	4 c. c.
Nitric acid	12 gtt.
Solution gold chloride (1:50)	3 c. c.
Water, distilled	(350 c. c. to) 600 "

The plates, after fixation with hyposulphite of sodium, or preferably cyanide of potassium, are well washed, and while still wet placed in the toning bath for one or two minutes. They acquire a blue-violet tone, which is found very suitable for lantern slides or stereoscopic transparencies. Dry collodion plates may also be toned in this bath, but the process is much slower, owing to the horny character of the collodion film, which resists the penetration of the solution. A bath of potassium chloroplatinite (1:1,400) slightly acidified with hydrochloric acid gives a blacker tone. A solution of

Water	500	parts.
Ammonium sulphocyanide	30	"
Sodium hyposulphite	½	"

added in equal quantity to the following:

Water	500	parts.
Solution gold chloride (1:50)	30 parts to 60	"

gives gray-blue tones. Platinum and gold toning is very successful with these baths.

[Continued from SUPPLEMENT, No. 1141, page 18236.]

THE FINDING OF THE REMAINS OF THE FOSSIL SLOTH AT BIG BONE CAVE, TENNESSEE, IN 1896.*

LONG before we had pulled the last bone out of the dust, our attention was attracted to the lower or older portion of the manure, which, owing to its peculiar consistency, I have called

FIG. 6.—SPECIMENS OF DISPLACED RUBBISH FOUND STUFFED INTO AND FILLING THE RAT HOLES.

1, 2 and 3, burnt sticks, pieces of charred cane, Arundinaria tecta, and charred hazel twig, Corylus americana, representing the ends of burnt out torches cast away by white men or Indians, often found at a greater depth in the layer than the sloth bones, having been intruded into the burrows from the surface by small animals.

LAYER 3.

(One foot thick.)

In it we observed no porcupine quills or tufts of fur, and for the reason below stated suspected that this lower subdivision of the dry excrement had become hardened and caked together just under the bones, into what it seemed reasonable to suppose had constituted the foothold of the cavern when the extinct animal appeared. Objects found in it, therefore, a further series of nuts, seeds, twigs, leaves, bat jaws, and fur described below, together with the dry carcass of the window fly, were to be reasonably regarded as older than the sloth.

FIG. 7.—RIB SHOWING SIGNS OF RODENT GNAWING, FOUND IN LAYER 2.

How may we better account for the character and position of this crust than by supposing that it represented that portion of the once lower floor where the carcass of the animal had for a time rested and into which the juices had filtered, caking together the coprolites during the consumption of the flesh by rats and porcupines?

This not improbable suspicion was strengthened when we considered the number of bones found at the spot, not simply the twelve exhumed by us, but those previously excavated by Priest and Johnson, now in Prof. Safford's possession, and we may add the eighteen other remarkable cartilaginous specimens, presumably from the same spot, at the Academy of Natural Sciences. If the whole combined series fails to duplicate or contradict the construction of a single fossil sloth skeleton, then all, because all indicate a young animal, and because all show cartilage as no other sloth bones elsewhere found have yet done, can be reasonably referred to the same individual animal. Many other bones, originally near or upon the surface, may have been removed by Indians or carried away by saltpeter diggers and lost. Rats may have made off with others. And, notwithstanding the fact that the sets belonging to the Academy and Prof. Safford, together with my specimens, may fail to reconstruct the animal's skeleton, the three sets together include enough bones to indicate that the creature had once lain there in the flesh. Because the tooth marks seem to refer to the work never of carnivora, but always of rodents, less to the efforts of large than of small animals not strong enough to have carried a skull such as Priest found, or a scapula like that at the Academy, from any other resting place in the cave, it seems reasonable to suppose that the bones reached their position by the most natural of agencies, that the sloth, lost or overcome by sickness in the darkness, had lain down to die at the place in question.

Reasonably doubting that it had shambled into the cave after the helpless club-footed manner of the modern ai or unau, shall we speculate further and imagine that the animal, less clumsy and sluggish than its modern South American relatives and presumably herbivorous from the structure of its teeth, was attracted to the spot by the smell of grass and leaves, brought thither by porcupines and rats? If not, we must believe that its choice of a deathbed in the only rat den in that part of the cave was a coincidence. But, however the position of the bones is to be accounted for, let us believe that if the carcass lay upon the manure, the number of visiting omnivorous rodents increased until the process of devouring the flesh had been succeeded by the gnawing of the bones.

If these suggestions explain how the bones came to be where we found them, we next ask, How old are they? When did they reach their position? An inquiry above all depending upon the study of the objects dug out of the earth with them. These are to be divided into three classes: First, objects of later age than the bones, or of doubtful antiquity; second, objects as old as the bones; and third, objects older than the bones. To the first class belong the torch ends of cane, Arundinaria tecta, hazel; fragments of clay, coprolites and bits of charcoal, mentioned above, as belonging to Layer 1, and second, objects artificially intruded into Layer 2.

OBJECTS OF LATER AGE THAN THE BONES OR OF DOUBTFUL ANTIQUITY.

The hoarding habit of the underground rat had helped our investigation at Big Bone Cave, but his burrowing perplexed and vexed us, confronting us with one of the dangers that often threaten exact observation in caves. The slowly formed accumulation of dry excrement had been undermined and disturbed by the tunneling of its makers against the right and left walls, where several rat holes were revealed by a variation in the texture of the neighboring layer. Pushed and wadded into these burrows (see Fig. 6) we found a bunch of moss, Hypnum; ten twigs from three to eight inches long, charred at the ends and evidently the remnants of torches used by Indians or white men; of the hazel, Corylus americana; five fragments, one of them charred and three inches long, of resinous yellow pine, Pinus mitis; a fragment of charred cane stalk, Arundinaria macrosperma, and another twig about eight inches long, not burned, of the cane, Arundinaria tecta; a gnawed pig nut, Hicoria glabra, and a shell bark, Hicoria ovata; a piece of hickory nut, Hicoria minima; a chokecherry stone, Prunus virginiana Linn.; a piece of hazel nut, Corylus americana; a fragment of an

* Abstract of paper by Henry C. Mercer, curator of the Museum of American and Prehistoric Archæology at the University of Pennsylvania, read before the American Philosophical Society.

acorn of the pin oak, Quercus palustris, and three pieces of winged seeds of the blue ash, Fraxinus quadrangulata, besides a piece of bark, probably hazel, and fragments of unidentified grass and bark. Besides these botanical specimens kindly identified (with all others referred to in this paper) by Mr. Stewardson Brown, of the Academy of Natural Sciences, of Philadelphia, Mr. S. N. Rhoads and Dr. Harrison Allen, of the Academy, have further settled the identity of twenty quills of the porcupine, Erethizon dorsatus, with its numerous excrements, and a piece of hair which had found their way into the holes, besides the upper jaw with portions of the skull of a bat, Vespertilio gryphus; and a lower and upper jaw, with teeth and cartilage attached, of a larger bat, Adelonycteris fusca. More excrements of porcupine seemed to have worked into the choked-up holes than were observed in the undisturbed portion of the layer, while with them was found a fragment of the brain case of a large mammal, smaller, according to Mr. Rhoads, than an adult bear. If this small specimen, not an inch in length, cannot be regarded as a portion of the remains of the megalonyx, it represents the only trace of any other large animal that we, or our guides previously, were able to find at the spot. But the objects found in the rat holes could not reasonably be associated with the bones. Though positively testifying to the presence of men as well as of animals in the cave, the charred torch sticks and other articles had been transported from their original position in the manure; and while it was certain that objects found in the superficial Layer 1 were more modern than the sloth bones, the rat hole specimens had lost their true time relation to the sloth. If not all intruded downward from above, and so presumably more modern than the bones, the collective age of all the specimens was doubtful and offered no evidence of the contemporaneity of man and the megalonyx.

On the other hand, no sign of disturbance was presented by the texture or contents of the middle portion of Layer 2. There the objects found at various points, and particularly close to the bones, seemed fairly to be regarded as ingredients of the deposit. Undoubtedly they represented plants and animals in existence at the time the bones had been deposited.

As we dug on with shovel, hands and trowels, narrowly observing that part of the manure (in many cases preserved by us in bags) lying in immediate contact with the bones, our work revealed by reasonable inference a series of

OBJECTS AS OLD AS THE BONES.

In the handfuls of refuse removed from close proximity to the sloth bones and preserved in bags were found, as identified by Mr. Rhoads (see Fig. 8) numerous tufts of the fur (also found in the rat holes), a com-

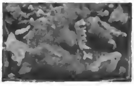

FIG. 8.

Mass of felted hair of rodents, together with a fine wool belonging possibly to the extinct sloth, found scattered through Layer 2, and often near the large bones. On this lies a jaw from the same layer of the bat, Adelonycteris fusca. The background shows the mass of rat manure and clay fragments characteristic of Layer 2. (Actual size.)

paratively large excrement quite unlike the other coprolites in size and shape, attributed by Mr. Rhoads to an herbivorous animal. Of the common coprolites previously mentioned, the larger and scarcer ones, containing fine shining particles of undigested hulls and skins of nuts, showed that the porcupine (Erethizon dorsatus), guided by other senses than sight, had been continually present during the formation of Layer 2. So testified a hair from the back of one of these animals (Fig. 7, object 16).

Eight beautifully preserved minute jaws and several little bones were identified by Dr. Harrison Allen as the remains of two kinds of still existing bats, Adelonycteris fusca (see Fig. 7, objects 17), and the smaller Vespertilio gryphus. Unfossilized and fresh looking, the bones, according to Dr. Allen, represent individuals which had fluttered through the congenial blackness of the gallery in geologically recent times, though we admit that the species referred to are ancient and probably existed at the epoch called post glacial.

In the very close neighborhood of the bones, as further identified by Mr. Stewardson Brown, we found fragments of the acorns of the red oak, Quercus rubra Linn. (Fig. 7, object 5), and of the white oak, Quercus alba Linn.; an acorn cup of the pin oak, Quercus palustris Duke; half of a nut gnawed by rodents of the thick-shelled, small-kerneled mocker nut, Hicoria alba Linn., Br.; several gnawed nuts of shellbark, Hicoria ovata Mill. Br.; and the gnawed nut of the butter nut, Juglans cinerea (Linn.). With these lay several fragments of winged seeds of blue ash, Fraxinus quadrangulata Mich. (see Fig. 7, object 4); two seeds of the horn beam, Fraxinus caroliniana Walt.; a piece of bark of the chokecherry; a seed of the gum Nyssa sylvatica; two small twigs of dogwood, Cornus alternifolia Linn.; fourteen little fragments of sticks and leaves and several pieces of bark undetermined, together with two wild cherry stones, Prunus pennsylvanica Linn.; while recorded as exactly under one of the sloth bones we pulled out a seed of the alder, Alnus incana Linn., and another of the horn beam, Carpinus caroliniana Walt., with a nut of the beech, Fagus americana Sweet.

There was no reason for doubting that these objects had reached their position at or about the time of the deposition of the sloth bones. Many of the nuts had been gnawed by cave rats (see Fig. 7, object 9), Neotoma magister, and the same agile pilfering animal, helped possibly by the porcupine, had doubtless dragged in by way of the roof holes, whether for nest building, for food, or in pursuance of its eccentric hoarding habits, many of the other objects scattered at various points in Layer 2. In this mass of excrements of the cave rat, [illegible] as they were, were crushed with some difficulty between the thumb and finger, together with the lesser porcupine coprolites, we found a hair from the back of the porcupine and a portion of the right side of the upper jaw with molar teeth of the cave rat (see Fig. 7, objects 16 and 15). Scattered irregularly through the layer as identified by Mr. Thomas Meehan and Mr. Brown lay an acorn cup of the Spanish oak, Quercus digitata (Marsh) Sud.; two fragments of acorns of the pin oak, Quercus palustris; a seed of the horn beam, Carpinus caroliniana Walt; and fragments of seed of the blue ash, Fraxinus quadrangulata Mx.; a fragment of hickory nut, Hicoria minima; of hazel nut, Corylus americana Walt. (see Fig. 7, object 18), and of beech nut, Fagus americana Sweet; a valve of the hop horn beam, Ostrya virginica Willd.; an awn of wild rye or lyme grass, Elymus Linn.; and a piece of the stipe of common brake, probably Pteris aquelina Linn. With these were two seeds of the blue ash, Fraxinus quadrangulata, others of the horn beam, Carpinus caroliniana, alder, Alnus incana, beech, Fagus americana, and gum, Nyssa sylvatica, two wild cherry stones, Prunus pennsylvanicus, a piece of chokecherry bark, twigs of dogwood, Cornus alternifolia, fragments of sticks (see Fig. 7, object 10) and leaves, and, according to Prof. Heilprin, one of the beadlike stem segments of a crinoid characteristic of the carboniferous limestone of the cave walls.

Judged by this botanical association, the age of the sloth remains was that of the flora of the surrounding hills, and that had not changed since seeds, nuts and bones came together. These specimens of well known trees and plants common to the forest of eastern North America still flourished upon the mountain above us.

But over and above the general significance of this fact, two objects discovered—the fur and the large coprolite—had a particular bearing upon the investigation.

Sometimes close to the bones, and generally scattered through the whole mass of manure in Layer 2, felted like tufts of carpet dust in an unswept room, lay wads of hair or fur (see Fig. 8, Fig. 4, object 4, and Fig. 7, object 14), exceedingly fine, slightly crinkled, with a reddish brown color, possibly due to contact with the cave earth. To what animal shall we attribute them? Certain fine bits may, according to Mr. Rhoads, be referred to the bat and a few straight hairs to the rat or porcupine. But as none of the rat fur has this crinkle, and as the under fur of the porcupine, according to Mr. Rhoads, is coarser than these specimens and always straight, this crinkled cave wool is attributable to neither animal. Shall we suppose it to be the under fur of the buffalo, or of any of the animals of the outer forest carried down into the cave in predominant quantity by rats? Is it sloth fur, and if so, why its extreme fineness? Where are the large, limp hairs, flattened in appearance and grayish white in color, characteristic of the living sloths? Shall we fancy the fossil sloth fine-furred as a seal? Yet if this discovered fur, which in all reason is contemporary with the sloth bones, be not sloth fur, what became of the sloth fur if the animal, as we suppose, perished here?

Leaving the significance of the fur in doubt, we are left to account for the comparatively large excrement of a herbivorous animal, likewise found in Layer 2, and altogether too large for the porcupine or cave rat (see Fig. 7, object 8, and Fig. 4, object 3). Because no other trace of a herbivorous animal of the size indicated was observed at the spot, and because of the herbivorous character of the sloth itself, it has seemed to Mr. Rhoads and myself possible to refer it, modern as it looks, to the latter mammal rather than to the exceptional presence of any other grass-eating creature at that part of the cave. On the other hand, it appears small for the great sloth, while its unbroken contours infer that it must have been transported when dry and hard, if we are to ascribe it to the deer or any animal of the outer forest, and suppose that the hoarding rat carried it down the roof holes into the cave.

In the compact lower portion of the manure, called Layer 3, forming, as before described, a crust suggestive of an older floor immediately under the bones, we found what by a reasonable inference were regarded as

OBJECTS OLDER THAN THE BONES.

Here in the dense mass of rat excrement rested a lower jaw of the bat, Adelonycteris fusca (see Fig. 9, object 7), as to which, in completing the list of bat remains found in the cave, Dr. Allen says that the bats here described seem larger than our common Eastern forms, though no marked variation in bats has been observed since the Pleistocene. Not far from this, and as kindly identified by Mr. C. M. Johnson, of the Wagner Institute, lay a well preserved dry carcass of the small "window" fly, common in the United States, first described in America by Say in 1828, as a new species, Scenopinus pallipes, but afterward recognized as identical with the European Scenopinus fenestralis Linn., the window-haunting adult insect of the so-called carpet worm. Entomologists have left us in doubt as to its life and habits, but we may suppose that its food quest led it so far underground as a consumer either of decayed wood, of dried woolly or animal matter (like carpets, under which its thin larvæ are often found), or, according to Williston, of the minute tineidæ, or the true wool-devouring moths, psocidæ, who would have attended the decomposition of animal skins and furs at the spot. However the fly's visit to the subterranean darkness is to be accounted for, there can be little doubt that it came down through the roof holes like the cricket above mentioned, while its position at this depth in the cave refuse would testify to its presence in America before the coming of Columbus, were entomologists not sufficiently sure that it had not followed the white discoverers in their ships across the Atlantic.

Near by were found bedded in Layer 3 small pieces of bark, nuts, grass, twigs and plant fiber unidentified, pieces of horn beam seed, Carpinus caroliniana (see Fig. 9, object 5); a seed of the blue ash, Fraxinus quadrangulata; two shellbarks, Hicoria ovata, and four fragments well gnawed by rodents; a gnawed bitternut, Hicoria minima, showing orifices for extracting the kernel made by a small rodent; and six pieces of the acorn of the pin oak, Quercus palustris (for all of which see Fig. 9). Judging by the absence of quills, hairs and coprolites, the porcupine had not visited the cave during the formation of Layer 3. Neither were we able to find in the latter layer the wads of fine fur so characteristic of Layer 2 above it; but if these were specimens of sloth fur, their absence is what we might have expected, since the fur of the sloth could not well have been scattered over a lower depth than the resting place of its carcass. The absence of these ingredients, these differences in character, together with its position, were sufficient to assign an older date to the lower layer, whether its crusted consistency was due to infiltration of animal matter or not. According to the order of formation of the different refuse, the lower layer preceded the upper, and the gnawed nuts, the seeds, thus ily preserving intact its delicate wings, comparatively modern as they seemed, had reached their position before the deposition of the bones.

Faint from continual inhalation of the noxious dust, we had lost the energy to excavate to its bottom, the last and lowest layer,

LAYER 4

(Depth unknown),

a mass of fine water-laid clay, broken in lumps ranging in size from six inches to a quarter of an inch in diameter, covering the whole floor of the gallery and evidently the equivalent of the nitrous earth which had been elsewhere removed. By their laminated structure the lumps gave evidence of their aqueous deposition, while hard as they now were, they dissolved immediately on immersion in water. Some pieces showed an irregular texture as of the caking together of various partially hardened muds, while others, in the opinion of Mr. George Vaux, Jr., revealed small fragments (irreducible by boiling in water) of adulterated carbonate of lime, probably aragonite. After digging several holes in the mass to learn that the manure had infiltrated downward for at least two feet through its interstices, we abandoned it where the configuration of the cave walls, widening as we went down into a crevice of unknown depth (see Fig. 3), rendered further work under the circumstances hopeless. We left with the reasonable inference that a depth of five, ten or fifteen feet would have laid bare the whole bottom, as it had been laid bare elsewhere in the gallery. Doubtless the process of drying, which succeeded the deposition of the layer by water, had broken it into lumps, between which the upper refuse, as remarked before, had penetrated, thus adulterating it without obscuring the fact that in its true constitution, for the eighteen inches examined, it contained no trace of man or animals.

Allowing the dust to settle for the last time, we turned away from the mysterious spot, and, threading

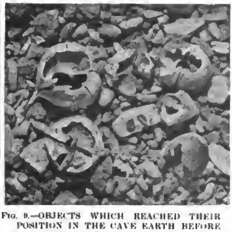

FIG. 9.—OBJECTS WHICH REACHED THEIR POSITION IN THE CAVE EARTH BEFORE THE ADVENT OF THE SLOTH BONES (Actual size.)

our way wearily through the chilly gallery, came with sudden shock upon the dazzling glow and severe heat of a Southern evening. With difficulty we toiled homeward, resting often in the warm woods.

At the last remaining point of significance we had examined layers which probably present all the evidence that will ever be collected as to the antiquity of the fossil sloth of Big Bone Cave.

Let paleontology enlighten us as to the probable character and habits of this animal, which we must reasonably regard as one of the common inhabitants of the American forest in Pleistocene times. Comparing the large vertebræ, the skull, the proportionately shorter claws and stouter limbs with the skeletons of the existing South American sloths, as here shown (thanks to the kindness of Dr. R. C. Chapman), we may well disbelieve that this animal hung, like the latter, back downward for days upon a single bough, or lagged in one tree or grove until moss formed upon its fur. How shall we imagine the creature, weighing from twelve to sixteen hundred pounds, moving from tree top to tree top in any known North American forest, when on the blowing of wind, according to the saying in Brazil, sloths travel. On the contrary, as the continual falling of so large an animal by the breaking of boughs is not to be imagined, we must deny the creature a strictly arboreal life, rather supposing, with Prof. Cope, that the boughs came down to the sloth than that the sloth went up to the boughs. In place of moss-covered clumps of motionless fur not easily distinguished from leaves, that a keen eye recognizes in South American tree tops, we fancy animals inhabiting the earth and proclaiming their presence by the crash of saplings and outlying boughs, as, rising upon their hind legs or climbing to the forks of heavy trunks, they tear their fodder to the ground.

If they despised water, like the ai and unau, they licked salt, as their fossil bones bedded in the Petit Anse salt pit in Louisiana and the mire of Big Bone Lick testify. As terrestrial animals continually on the defensive against the foes of the forest, probably little less active than bears, the great sloths would hardly have rolled helplessly upon their backs when attacked like the unau or yielded up their dinner with a melancholy drone. On the contrary, though we must imagine them inoffensive and by no means agressive

enemies of animals or man, the thrust of the powerful arm, and scratch with the claws that brought down saplings, might well have defended them against powerful and active foes.

A categorical demonstration that this individual animal was a contemporary of the geologically recent Indian in Tennessee must be abandoned. But the reasonable inference of such association remains. Though the human handiwork, in the form of charcoal and torch refuse (except the rat hole specimens), lay really on the surface (Layer 1) from six inches to one foot above any sloth bone found; we may justly be satisfied with the recent significance, broadly regarded, of the whole record, and with the absence of plants and smaller animals of any extinct or positively ancient form.

Gradually a thin sprinkling of rat excrement upon the clay floor had thickened into a dry, dense mass. Before the deposit had reached a depth of two feet the sloth had appeared and perished, and while the duration of this manure-making process, which finally, rising round the bones, covered them to a depth of one foot or eighteen inches, cannot be safely guessed at in terms of centuries, there can be no doubt that it is geologically recent, and that its construction which preceded and followed the deposition of the sloth bones is continued by the visits of existing cave rats at the present day. The manure formed, the leaves, nuts, grass and seeds found their way in, without the interruption of any important interval of time or geological event changing the topography of the cavern. The roof holes had probably remained open continuously. The subterranean temperature of fifty-five degrees Fahrenheit, with an extreme dryness, had probably persisted. The same flora had continued to flourish upon the mountain. The same visiting animals had continued to find the same plant food, while the same bat species had sailed in from the open entrance.

Had these bones lain within reach of the percolating chloride of lime, this mineral, filling the cavities vacated by animal matter, might have hardened them as cave bones are often hardened, but lying where we found them, we may well doubt whether they ever would have fossilized. Under such circumstances, let us believe that a nut, a seed, a leaf, or even a fly, would preserve the freshness of its structure for a long time, and hence that the interesting remains found with the bones may not be so modern as they seem. With this reservation, and without attempting to deal definitely with dates, it seems safe to class the evidence not only as geologically but as historically recent. Not more ancient in appearance, not more brittle than the bones of animals found by me in the Indian midden heaps of several caves, the position of the bones in the upper and later part of the rubbish, their gnawed condition and their association, as described above, offer nowhere a suggestion of great antiquity. Separated from all association with the remains of other Pleistocene animals, they fail to lend the color of antiquity to the situation. On the contrary, like the peccary bones found at Durham Cave, like the remains of tapir and mylodon discovered in Lookout Cavern, they seem modernized by their surroundings. Let us infer that we have found a species which, long surviving its day and earlier relationship, had become an anomaly; that we have modernized the fossil sloth, if we have not definitely increased the antiquity of the Indian hunter, whose first coming the animal doubtless witnessed in the woods of Tennessee.

THE LIORET PHONOGRAPH.

At the end of May we entered a vast court lined with five story houses in Rue Thibaud, just beyond the Luxembourg. Every one was at the windows listening to a speech delivered in a loud voice that was somewhat too measured to suggest that of an open air orator. We listened to this sonorous voice, but looked for the orator in vain. Finally, at the back of the court, we perceived what seemed to be a small stage covered with a red carpet. He is there, we thought, and so we went forward.

The stage changed its aspect; there was a tripod half hidden by red velvet upon which was placed a sort of casket, and, in front, a large trumpet of polished metal. It was superfluous to look further; the orator was a phonograph, and such a one as we had never before heard. The Edison phonograph and its successors are certainly very extraordinary, but with these it is necessary to approach the instrument and place the ends of a tube in the ears in order to hear, or else stand a few feet distant from a trumpet that distributes the sounds. This time, it is a very different thing. The voice is distinctly heard in the open air, at a distance of twenty-five yards, with its pretty nearly natural timbre. The illusion is complete. One would affirm that it was really some one who was speaking, and who was inflating his voice in order to increase its range. Every one, in the course of his life, has heard a speech on the occasion of the inauguration of a statue or of some other public ceremony. Such was the speech delivered in the court. And the illusion was rendered the more perfect by the noisy applause that broke forth from all the windows of the houses. It is to M. Lioret that is due the credit of having rendered the phonograph truly practical.

The Lioret phonograph, which is very simple in construction, possesses an intensity of sound that has never before been obtained, and, when everything works well, the articulation is extremely clear and the timbre relatively good; and the apparatus lends itself faithfully to all reproductions—speeches, operas, operettas, duos, trios, military marches, etc.

Scarcely had the phonograph ceased its speech in Rue Thibaud, when we suddenly heard the beating of drums and a blast of clarions. Then came a player of the biniou (a sort of bagpipe), an air on a hautbois, etc. Music boxes are now done for, since hereafter every one will be able to have at home the singers that he prefers and to hear operas and comic operas executed. The apparatus is at present capable of operating for more than five minutes, and, by means of a very simple artifice, for more than an hour. We shall therefore be able to hear an entire act, just as with the theatrophone.

The apparatus consists of the following parts. A tripod like that of a camera, which is concealed by a beautiful cover, and upon which is placed the apparatus provided with a large sonorous trumpet. The celluloid rollers, which are a few inches in length, are inclosed in a morocco leather box. Each roller carries the preferred morceau condensed into a few fractions of an inch, and corresponds to the old perforated band of the pianista. The roller is adjusted upon the apparatus, one pushes a button, and, presto! perceives almost the respiration of the singer.

The apparatus can be folded up and taken on a moonlight night to a park and be installed under the trees and amid flowers in order to allow the phonograph to reproduce the voices of our most celebrated artists. We have heard "La Dame Blanche" in a park, with a violin, violoncello, etc., accompaniment. This does not happen every day, even in the country.

This new instrument is truly curious, because the intensity of the sounds is such that it may be concealed in a corner, and give the illusion of a person speaking at a distance. It was recently operated in a garden at Ville d'Avray, where it caused a crowd to gather at the gates, and passers-by asked again and again where the singers were.

Such, in brief, are the effects of the new phonograph; and now for a few descriptive details.

The principle is well known: A person speaks or sings before a thin disk that is capable of vibrating and is provided with a point in the center. The voice causes the disk to vibrate, and the point traces fine lines upon a roller of soft material which is made to revolve very regularly. This is the registering part. Reciprocally, when the roller is made to revolve in the same way before a point fixed to a vibrating disk, the sounds are reproduced integrally. The improvements due to M. Lioret are important. They concern the movement, the motor, the transmission of motion, the cylinder, the resonator and the amplifying trumpet.

The movement that carries along the roller must be extremely regular. This is produced by a very accurate piece of clockwork, which, as a general thing, is actuated by a 13 pound weight suspended from a pitch chain that runs over a barrel fixed to a toothed wheel of large diameter that controls the revolution. The movement is further regulated by a small fly wheel of which the wings open out and give so much the more resistance in the air in proportion as the revolution tends to quicken. Upon the fly wheel a small piece of rubber fixed to the end of a lever acts as a brake. Upon depressing the lever, the fly wheel is set free and begins to revolve. The apparatus is thus set in operation.

Upon the side there is a small rubber band which connects two wooden pulleys and transmits the motion. This band constitutes one of the characteristics of the new apparatus. It is a transmission belt which prevents any vibration of the apparatus that might affect the revolution of the roller and be communicated to the resonator.

The vibrating disk is very wide and is set into a sort of flat box forming a resonator. The trumpet is fixed to the latter. Finally, the point of the style that enters the grooves in the roller is of sapphire, and, consequently, very hard. M. Lioret, who is making continuous researches with a view to improving his apparatus, has recently modified this point, and given it a new form. It is no longer a sharp point, but a rounded one. The effect of this change is important.

The trumpet whence the sounds proceed has also been modified. Toward the middle of its length, in an aperture formed in the side, there is fixed a small piece of metal by means of a screw. This simple addition gives an extraordinary result, the intensity of the sound being thereby nearly doubled and the clearness of the emission very much increased. Finally, when it is desired to operate the apparatus in a large auditorium, the amplitude of the sounds and the clearness of the articulation may be further increased. M. Lioret places in front of the first trumpet a second and larger one of thin metal and in the form of a truncated cone. The effect is singular. The range of the sounds is immediately tripled and the words reach the ear with remarkable clearness. This fact has been proved at the Trocadero, where the acoustics of the hall are pretty bad, but where, nevertheless, a phonograph placed upon the stage has been heard perfectly from all parts.

One word more as to the rollers. M. Lioret makes these of celluloid. This is an advantage, since wax rollers become soft through heat and are put out of service by a fall or almost any slight accident. With celluloid, it is possible for every roller to last a century. A fall does not harm it, since it is solid.

The apparatus, it is true, is not reversible, that is to say, it is impossible, as in the old phonographs, for a person to register songs and speech for himself. The rollers have to be procured already prepared, and none but these can be used in the apparatus. The difficulty might be overcome if the inventor desired it, but it is very evident that he does not care to do so. He prefers to sell his rollers, and it is thus certain that they are properly registered.

Upon the proper manufacture of the rollers evidently depends the success of the operation of the apparatus. The manufacture, moreover, is interesting. The celluloid is softened by a secret process, and then, in the form of a roller, is turned and polished with the greatest care. The roller thus worked is carried by an axis to which is given an absolutely regular rotary and

Fig. 1.—EXHIBITION OF THE LIORET PHONOGRAPH IN THE LARGE HALL OF THE TROCADERO

Fig. 2.—GENERAL VIEW OF THE PHONOGRAPH.

Fig. 3.—DETAILS OF THE POINT AND REGISTERING CYLINDER.

horizontal motion produced by a dynamo. A singer places himself in front of a trumpet, which directs his voice upon a vibrating disk of which every motion is followed by a graver. This latter penetrates the softened celluloid and produces therein depressions that are almost invisible and that will be used by the phonograph for reproduction.—La Nature.

APPLICATION OF ELECTRICITY TO RAILROADS NOW OPERATED BY STEAM POWER.*

By N. H. HEFT.

THE New York, New Haven and Hartford Railroad Company owns and controls about 2,800 miles of main line railroad track in New York, Massachusetts, Rhode Island and Connecticut, of which about 16 miles are operated by electricity on the third rail system and 14 miles on the overhead trolley system.

The first line to be equipped by the New Haven Company was a purely summer road, operated about four months in the year only, through a narrow peninsula running out from the mainland on the Massachusetts coast from Nantasket Junction to Pemberton, a distance of about 7 miles of double track. This line was chosen partly because the main line operation would not be interfered with in case of trouble with the electric trains, and partly because of the existing heavy summer traffic, which would put the new apparatus and the feasibility of the entire system to a severe test. An overhead trolley line was built, with center pole construction, and everything made very strong and more substantial than was at that time found in any street railway work, to our knowledge.

The line was operated for the first summer with excellent success, and all fear of trouble having disappeared, an extension of 3·6 miles was made on the main line of the company's Plymouth Division, this section being operated by the third rail system.

In December, 1896, we commenced work on a new line running from Berlin, Conn., through New Britain to Hartford, a distance of 12·3 miles, 3 of which, from Berlin to New Britain, is a double track, and the remainder, from New Britain to Hartford, a single track. A power station was built at Berlin, one end of this line, partly because of a desire to test transmission of power to a considerable distance and partly because Berlin is the center of several radiating lines, which may eventually be put into operation by electricity.

We have learned very thoroughly, in our street railway experience, the lesson of the importance to any transportation agency, working in a thickly populated territory, of uniform fares and a frequent and regular train service—of a train service which requires no printed schedule to enable people to know when cars may be found in waiting.

On its Nantasket Beach line the New Haven Company gave, during the last summer, a regular half hour service from 6:30 in the morning until 11:30 at night. The fares charged on the Nantasket Beach line before the advent of electricity were 10 cents from Pemberton to Nantasket and 18 cents from Nantasket to East Weymouth, a total of 28 cents from Pemberton to East Weymouth. With electric traction they have been placed at a uniform rate of 5 cents from Pemberton to Nantasket and 5 cents from Nantasket to East Weymouth, a total of 10 cents from Pemberton to East Weymouth. Under these new conditions the traffic has increased enormously on this line; the summer of 1895, the first of the electrical operation, showing an increase of 92·6 per cent. over the previous summer in the number of passengers carried; the summer of 1896 showing 45·1 per cent. increase over 1895, while in the summer just passed we have carried nearly three times as many passengers as in the last year of steam operation.

The operation of the line from New Britain to Hartford was commenced in May last, with a regular half-hour train schedule from 6 in the morning to 11:30 at night, and with a uniform fare of 10 cents each way, instead of 28 cents, the former charge. The electric line carries through passengers only between Hartford and New Britain, the passengers for the five way-stations being carried by the regular steam trains running on a parallel track. For ordinary everyday service a single open-motor car was used during the past summer, while for extra loads light double-truck trail cars seating seventy people were attached. On rainy days a standard close passenger coach was hauled by the open-motor car. On holidays and Sundays the cars pulled two trailers, the entire train seating nearly 250 passengers. About the middle of August steam service on the Berlin-New Britain branch was discontinued, and the traffic has since been handled entirely by electricity. Sixteen trains each way per day are run, connecting with steam trains.

Under the conditions named on the Hartford-New Britain line we have carried during the three summer months 400 per cent. more passengers than we carried through the corresponding months of last year.

I do not suppose that any but a trained railroad man can understand the impossibility of operating trains and maintaining schedules by steam locomotives in the way that has been done by electricity at Nantasket Beach last summer. There are a great many curves on the line and several grades. There are no excessively sharp curvatures or steep grades, and it is not here that the trouble has come. The difficulty is found in the fact that there are no less than seventeen stations on a line only 10·6 miles in length, or an average distance between stations of but about 0·6 of a mile. To make a run of 10 miles with sixteen stops in twenty-six minutes; to be obliged to do this in order to connect with boats arriving at regular half-hour intervals, and to keep out of the way of frequent regular steam trains on the main line of the Plymouth Division; to allow but four minutes at each end for unloading, switching (including running around trail car), and loading, and to do this day in and day out, in regular service, through an entire summer—these are things which cannot possibly be accomplished by steam locomotives.

Now the reason why electricity can do this and steam cannot is found in the tremendous accelerating power of properly designed electric motors, with rotary motion, as compared with reciprocal motion of steam locomotives. A 60 ton train, for example, in running from Windermere to Allerton, a distance of only 1,800 feet, reaches a maximum speed of 31 miles per hour, while in the longer run from Power Station to Nantasket Junction, a distance still of but 5,808 feet, a maximum speed of 30 miles is reached. The entire distance is covered, in regular service, at an average speed of 24·6 miles per hour, including stops.

Between Hartford and New Britain the 9·3 miles distance is covered regularly by motor cars with two trailers in from 18 to 20 minutes, an average speed of from 28 to 30 miles per hour, while, with a special high-geared motor, a maximum speed of over 60 miles has been made, the entire distance of 9·3 miles being covered in ten minutes. On this line a 52 ton train often reaches a maximum speed of 50 miles per hour. The current is cut off at twenty-nine grade crossings when single-car trains are run.

It is worthy of note, in this connection, that the line between New Britain and Hartford is in direct competition with a trolley line between the same points, but following a more circuitous route. The schedule time of trolley cars is fifty-five minutes, as against our time of less than twenty minutes, and the rate of fare is 15 cents (including a transfer given for use on the street railways of either city), as against ours of 10 cents for the straight run between the two cities only. The ownership of right of way has a very important influence upon speed and competitive conditions under circumstances like these.

The type of car selected for any good transportation service has a direct bearing upon the development of traffic and maximum gross receipts. It has been difficult for steam railroads to depart far from the long established custom of closed passenger coaches of the present standard type, and to adopt open cars, on account of the disagreeable effect on passengers of the smoke and gases from engines. This has naturally thrown a great deal of traffic to competing street railway lines running open cars in summer, on account of the greater comfort of the open car.

With electric operation open cars in heavy railroad practice are possible, even at considerable speed, particularly if the front of the car is closed in with glass, and both at Nantasket Beach and on the Hartford-Berlin line we have used heavy open cars with great success.

The motor car, which we have so far used, we do not consider, by any means, the final type, and even now we have in mind plans of combination cars which we believe will be, on the whole, well adapted for railroad work. The present motor car is very heavily built, with floors of a height equal to that of our standard passenger coaches. It contains sixteen cross seats, capable of seating ninety-six passengers, and the entrance is from either side, with three steps. Each car has two heavy railroad trucks, one of which is equipped with two 125 horse power motors. The total weight of the motor car is thirty-two tons, and the trailer car of the same type weighs twenty-five tons. The motors which we have used up to date have been of a type common in heavy elevated railway work. These motors have often been in service for several consecutive days, making 325 miles each day, without apparent injury. We found the motors we are using already in the market when we commenced our experiments, and, until recently, no attempt has been made by us to specify changes. The experience gained with these motors has served as a basis for building larger and heavier types, better adapted for the severe work which they will be called upon to fulfill to meet our requirements. An important point which we shall specify in new motors is that they shall have the most perfect ventilation possible. The efforts of manufacturers have been hitherto directed toward completely incasing the motors, so as to make them waterproof, but in doing this ventilation has been sacrificed.

We have found it beneficial to blow out our motors several times during the day by means of a blast of air from a hose pipe connected to our air brake reservoir, but this is, at best, but a makeshift.

It is very difficult to dispose of all the necessary cables, wires, brake rods and chains, air brake cylinders and apparatus, switches and other car controlling mechanism in the limited space beneath the car floor, as may be readily imagined by those familiar with street railway work. As a consequence, there has always been more or less controversy between those responsible for the placing of the different portions of the equipment as to who shall have the first right to a given space, perhaps hardly a half a dozen square inches in section. There is also more or less trouble with abraded wires, short-circuited shoe hangers, etc., and for our future work we are making an effort to simplify this mass of equipment mechanism by putting some of it, particularly the wires and cables, in a space between the true floor of the car and a false floor several inches below, specially provided for the purpose.

For operating heavy trains of this character, where currents of from 300 to 1,000 amperes are sometimes used, the controlling apparatus must be massive and strong in every part, and the greatest care must be taken to prevent arcing. We have had no trouble with controlling apparatus on our regular equipments, and we consider this branch of the apparatus well perfected.

The danger to station and car apparatus from lightning discharges, which is so important a factor in street railroading where the overhead system is employed, is avoided in third-rail work, since the third rail is so close to the ground that it is practically a lightning arrester itself throughout its whole length.

The problem of braking, which is so important in street railroading, is even more so with us, since the train weights and speeds are enormously greater. The regular Westinghouse air brake system, with engineer's valve, is used on our electric trains, but instead of steam air compressors we have an electric motor compressor, controlled by an automatic regulator which has given excellent satisfaction.

Our experience with trolleys on the overhead line at Nantasket Beach, originally put in two years ago, has not been satisfactory. We find it quite impossible to prevent the destruction of trolley wheels by almost continual arcing when attempting to take from the wire the heavy current required in starting and during acceleration, as well as the smaller currents taken at the maximum speed. There has been a good deal of trouble, moreover, in keeping the trolleys on the wire in making speed and taking curves, and many trolley poles have been broken. The trolley difficulties have not interfered with the continuous operation of our line, but the cost of replacing wheels and poles has been rather large.

These difficulties have had an important influence in causing us to reach a decision in favor of the third rail. The contact shoes, which take the current from the rail to the motor circuit, have given, on the whole, good satisfaction, although they are occasionally carried away by the approach blocks at grade crossings when these blocks happen to be slightly misplaced so that the shoes strike them at the wrong angle. The contact shoes are suspended by cast iron links, which are intended to be weak enough to allow the shoe to break away easily without doing damage to the frame work of the car. The trail cars are also equipped with shoes, and connected with the circuits on the motor car by means of flexible couplings, and it is possible therefore, when the cars are run in train, to bridge the longest gaps found at grade crossings and switches, so that it is not necessary to turn the current off on approaching these. This arrangement makes our trail cars independent of the motor car for heating and lighting.

It will be noted that the Nantasket cars have two trolley poles, as well as contact shoes, and the change from trolley to third rail simply means the pulling down of the pole and the closing of the third rail switch.

Our third rail and return circuit experience will, perhaps, be of value to both street railway and railroad managers, as we have undoubtedly made a wide departure from established methods.

First is the question of insulation. The third rail has a potential of 600 volts above the ground and rests upon creosoted wooden blocks doweled into the ties, its eaves being only $1\frac{5}{8}$ inches above the tie. Now it frequently happens that water accumulates 2 inches or more in depth over the ties, and, if it were not for our experience to the contrary, we would naturally suppose that, under these circumstances, the line would be directly short-circuited between the third and service rails through the water, the distance being but about 2 feet each way. Nevertheless, we have been able to operate our road without the slightest difficulty when this has happened, and nothing unusual has been noticed at the station, nor has the electrical output, as registered by the recording wattmeter, been abnormal. At Berlin we have watched the ammeter closely when we knew the tracks to be submerged in two places 10 miles apart, during a heavy rainstorm, and have found that the leakage was almost imperceptible when both cars on the line were at rest and their air pumps out of circuit. At that time the wattmeter was standing still. Of course, if a long length of track were submerged, the leakage might become serious, but we have yet to learn how much is necessary to accomplish this result.

We aim to so connect our third rail lines and the service rail return as to have a practically complete metallic circuit of extremely low resistance; as far as possible insulated from the ground. We do not believe in grounding our track, and, though ground plates are placed at the station, connected to our generator, by far the largest proportion of the return current comes through the cables connected directly with the track, the percentage coming from the ground plates being extremely small.

The joints of the third rail are bonded by long copper plates, firmly bolted to both sides of the joint, sixteen bolts being used in all. These copper plates are tinned before being put into position. Owing to the large area of contact surface, the presence of rust on this surface does not materially interfere with the conductivity of the joint, as shown by accurate tests.

The service rails are bonded with the greatest care, four copper leaf bonds, having a cross section of copper equal in conductivity to that of the rail, being used. These bonds are inserted in the base of the rail instead of the web, so as to prevent breakage through play at the joints. The copper leaves are cast into end piece blocks in such a way as to weld them thoroughly together in the blocks. The latter are formed into a hollow cylinder, 1 inch in diameter, which passes through a hole in the flange, and by which a large area of contact is secured. Taper pins are driven into the inside of this cylinder from the top of the flange, and the connection made is very perfect. Careful tests have shown that the joints of both third and service rails have now a slightly greater conductivity than an equal length of the rails themselves.

A few words about the danger of the third rail system would be perhaps in order. There have been many cases of people who have stepped from the ground to the third rail without feeling the current, and anyone can step upon it from a dry tie without the slightest effect. On all except wet days our employes work about it without trouble, avoiding, of course, putting themselves in direct contact with both service and third rails, but not infrequently "monkeying" with the current in such a way as to get shocks of more or less severity in a sort of horseplay. On wet days they refer to the third rail as being "lively," and are inclined to let it alone. Many of our employes have, however, received the heaviest shock possible to obtain, time after time, and care little about it, though those who are more influenced by electric shocks than others are sometimes thrown off their feet, but recover fully in a few minutes. We do not say that the third rail has no dangers, but we do not consider the danger as being at all serious or one which should interfere with the extension of the system.

As a result of exceptional care which we have taken in bonding our third and service rails we have found it unnecessary, in any third rail work so far done, to use copper feeders, in spite of the fact that we are obliged to transmit current from Berlin to Hartford, a distance, as before stated, of 12·3 miles straight away from the power station. This work is made up as follows: From Berlin to New Britain, a distance of 3 miles, there is a complete double track electric road, with two 93-pound third rails and four 74-pound service rails, all most carefully bonded as described above; from New Britain to Hartford, a distance of 9·3 miles,

* Abstract of paper read at the convention of the American Street Railway Association, Niagara Falls, 1897.

there is one complete electric track, with 100-pound third rail and 70-pound service rails, all carefully bonded, in addition to which we have connected to the service rails of the electric track the rails of the second track, paralleling this the entire distance, at various places, in order to get the benefit of whatever conducting power there might be in this track connected only by its fishplates at the joints. As a result of this work, we are able to run two trains of 52 tons each on the New Britain and Hartford line, with an average loss of but 20½ per cent. The current output of the station at such a time averages about 300 amperes, with a maximum flow of about 700 amperes at a pressure of 600 volts. Of course, if the service were heavier, so that more cars would be required, it would undoubtedly be necessary to reinforce the third rail with feeders.

In spite of the fact that the general conditions of operation do not point to a low cost of power, because of the fact that we are working neither station at anywhere near its full capacity, I suppose we are, as a matter of fact, producing power more cheaply than can be done in any power station in the country using coal as a fuel, the reason being that we are burning sparks. "Sparks," as we are accustomed to call them, are the half-consumed coal dumped from the extension front of locomotives at the company's various round houses. Nevertheless, there is a great deal of steam generating value in these sparks, as we have found by experience, and they are being carried on the company's cars to our stations at Berlin, Nantasket and Stamford, and charged to the electrical operation at the cost of freighting (including the usual profit to the company for transportation), plus the cost of loading and unloading, a total charge of 70 cents per ton delivered.

In order to burn these sparks we are obliged, of course, to make some changes in the furnace arrangements, chief among which is provision for the introduction of live steam under the grates, forming a blower or forced draught as well as providing the water which, in decomposition, furnishes the oxygen and hydrogen gases, which increase greatly and facilitate in combustion of half burned coal and add enormously to the furnace heat. We originally supposed that some form of shaking or self-cleaning grate would be necessary in burning sparks, but have found in practice that, with ordinary grates together with the steam blower, there is no difficulty. In our experimental days, it was thought that it might be necessary to use a proportion of ordinary soft coal with the sparks, and we did so for a while, but it was not long before our firemen were educated to burn sparks only with entire ease, and no other kind of fuel is now used by us. Of course we have to use a greater weight of this half consumed coal than would be the case with new coal, but still the economy is great, as a good quality of run-of-mine coal costs us in Connecticut about $3 per ton delivered at power station.

As before stated, our Berlin plant has not been run as economically thus far as it will be when a greater load is put on the engines, and it will seem to be in the interest of economy to run compound condensing. At this station the cost of fuel, with the use of coal, has been 9 mills per horse power hour, or 12 mills per kilowatt hour. Using sparks as fuel has reduced this cost to 3 mills per horse power hour, or 4 mills per kilowatt hour.

It is very difficult, of course, if not impossible, to make any direct comparisons between the cost of motive power for electric railroading and that for steam railroading, on account of the different way in which the trains are made up. The best criterion would be the cost of motive power per ton mile hauled, but even here the results would be of little value on account of the wide difference in conditions, and, as a matter of fact, we have never attempted to make such comparisons.

I have tried to give you, as briefly as possible, some of the results of the pioneer work which the New Haven Company has been doing in heavy electric railroading. They are roughly stated, and we cannot pretend that they are in any way conclusive as affecting general railroad practice. For ourselves, however, we have formed some definite ideas as to what is possible for us to accomplish, and our plans for the future are being made with great care by President Clark and the Board of Directors, with the intention of dealing with the new transportation conditions which confront us in a broad minded and progressive way. It is felt that a great transportation agency of this character owes it to the public from which it has obtained its franchises to furnish the best possible service and to make the most of the natural advantages which it possesses.

There will always be room, doubtless, for railroads of two characters, the one operating on a purchased right of way, where trespassers can be kept away and high speed obtained, and the other operating on streets and highways, where passengers can be taken up and let off at their own doors. It is possible that, in some thickly settled districts, such as are found in New England and the Middle States, where population groups almost touch each other, these two classes of service may occasionally be performed by the same agency, but there is no reason, ordinarily, why there should not be the most amicable and friendly relations, and not infrequently of a business character, existing between steam railroad and street railway companies.

Bicycle Rim Cement.—A good thick shellac varnish with which a small amount of castor oil has been mixed will be found a very excellent bicycle rim cement. The formula recommended by Edel is as follows:

Shellac	1	pound.
Alcohol	1	pint.

Mix and dissolve, then add

Castor oil	½	ounce.

The castor oil prevents the cement from becoming hard and brittle.

A cement used to fasten bicycle tires may be made by melting together at a gentle heat equal parts of gutta percha and asphalt. Apply hot. Sometimes a small quantity each of sulphur and red lead are added (about 1 part of each to 20 parts of cement).—Pharmaceutical Era.

M. BAZIN'S ROLLER STEAMSHIP.

No invention involving so radical a change in the construction of steamships has been put before the public since the first steamers were produced at the beginning of the century as the "roller" steamship of M. Bazin, the French engineer. Hitherto, the hull of a ship has been built more or less egg shaped, but the Ernest Bazin consists of a flat rectangular deck supported upon twelve disks or wheels. The vessel, which was launched last year, is only an experiment, so to speak, and is therefore small, being only of 274 tons burden. M. Bazin hopes in time to build a steamer large enough to cross the Atlantic. Meanwhile, he has been trying the experimental steamer. The Ernest Bazin has six floats or wheels; her length is 131 meters, and breadth 39 meters. On the deck are the cabins, saloons, machinery and boilers. The whole idea pursued in the construction of the vessel has been the reduction of friction with a consequent increase of speed at a minimum of expense and effort, by rolling through the water instead of cutting through it. Each of the rollers has a displacement of about 45 or 46 tons. The rollers serve, it will be seen, not only as part of the means of propulsion, but also take the place of the hull in an ordinary vessel. The Transatlantic liner which M. Bazin proposes to build is to have four of these wheels instead of three as in the experimental steamer. The shafts for making the wheels revolve pass below and across the platform, and, like the wheels, are of steel. M. Bazin argues that in order to obtain a maximum rate of speed there must be a corresponding relation between the rotary force and the propelling force, and his steamer is fitted with two independent sets of engines, one to drive the rollers and the other to propel the vessel forward by means of a screw. Among other advantages claimed for the vessel may be mentioned the small amount of rolling and the ease with which repairs to the hull can be attended to, docking being unnecessary. Then again it is urged that if a wheel is damaged the injury can be made good without stopping the vessel, for the injured wheel and its corresponding wheel on the other side can be stopped while repairs are done, while the others can continue their course through the water. On July 29 the Ernest Bazin went on a trial trip from Havre. On board her was Sir Edward J. Reed, who went to ascertain from personal observation how the vessel behaved, and more especially in what degree the speed would be affected by applying part of the available steam power to the rotation of the rollers instead of to the direct propulsion of the vessel.

Sir Edward Reed's report to the Société d'Etudes et d'Exploitation des Navires Rouleurs Bazin has just been issued. The vessel's engines are of 350 I.H.P., and these engines work both the screw machinery and the rollers jointly; so that in this vessel of 274 tons displacement there was only about one-seventeenth of the steam power requisite to drive a vessel of similar size at thirty knots, and one twelfth of that necessary to drive her twenty-seven knots. Nothing but a very low speed could, therefore, be anticipated of the vessel, owing first to her smallness, and secondly to her low steam power. A small vessel is, in Sir Edward Reed's opinion, very unsuited to the application of the Bazin system. The rollers are of necessity too close to each other, and consequently the systems of waves which the onward movement of the rollers creates and sends off on each side of each roller very soon reach each other and cause reactionary turmoil, which is unfavorable to smooth and easy progress, whereas in a much larger ship the progress would be much less interfered with by this cause. Then, too, so small a vessel is necessarily shallow, and no proper immersion can, under ordinary conditions, be given to the screw propeller, and a screw propeller works at a very great disadvantage when too near the surface. However, in spite of the disadvantages under which the system was tried, the vessel surprised Sir Edward Reed by its performance, and he gives the following results of the experiments made on the trip:

"We began the trials off Havre with very small power and speed. In the first two measured runs only about 112 I. H. P. was exerted by the screw propeller engines, giving, with the rollers at rest, a speed of 4·25 knots. Keeping only the same propelling power at work, but causing the rollers to revolve seven turns a minute by the application of 25·08 I. H. P., we obtained a very remarkable increase of speed, which rose to over 6 knots (more exactly 6·39 knots). I have calculated what the increase of speed would have been had this 25·08 I. H. P. been added to the screw engines instead of being applied to the rollers, and I find that by this means we should merely have added 0·55 of a knot, thus raising the speed from 4·25 to 4·8 knots only.

"In the next experiment the power exerted upon the screw was increased to 295 I. H. P. and the roller power to 34·2 I. H. P., the rollers revolving nine turns per minute. I calculate that with the rollers at rest, the increase of horse power upon the screw should have raised the speed from 4·25 to 5·8 knots. The actual speed attained was 6·81 knots, giving an excess of speed due to the revolution of the rollers of 1 knot. It will be seen that this gain is not quite so much as in the previous case, although the power applied to the rollers was somewhat increased—a fact that may be conjecturally accounted for in several ways; but there remains the remarkable fact that the vessel steaming at say 5·8 knots only, with 295 I. H. P. applied to her screw, is increased in speed by fully a knot by the application of only one-ninth of that power to her rollers! A further, but small, increase of speed (from 6·81 to 6·97 knots) was obtained by increasing the power on the rollers to 52·2 I. H. P. Small as this increase was, it nevertheless points to the fact that the additional 18 I. H. P. was much more efficient when applied to the rollers than it would have been if applied to the screw propeller."

THE ROLLER STEAMER ERNEST BAZIN LEAVING HAVRE ON A TRIAL TRIP.

In conclusion, Sir Edward Reed says:

". . . There can be no doubt whatever that the experiments conclusively demonstrated that the Bazin rollers furnish an effectual means of greatly reducing the friction which a floating body encounters in its advance through the sea, and friction is certainly one of the most serious of the elements which compose the resistances encountered. It does not, of course, remove or evade all friction, for all the ascending and descending parts must of course encounter some friction even in still water; as must also those immersed parts of the roller which are not retreating, so to speak, or moving sternward, with precisely the same velocity as the ship advances; but, as regards these latter, it must be remembered that all are moving sternward at some velocity, and therefore all are avoiding, to some extent, the resistance due to friction. It has been conclusively shown, I think, that on this question of reduced friction and consequent increase of speed or decrease of power, M. Bazin's views have been in a general sense fully established."

The reports of a number of pilots who have had charge of the vessel on various occasions go to show that she behaves well in a fresh breeze and rough sea, and that she is an exceptionally dry boat and easily handled. We are indebted to the London Graphic for the engravings and particulars.

PNEUMATIC LOCKS FOR CANALS.*

By CHAUNCEY N. DUTTON, New York.

THE first canal lock was built about 1490 by Leonardo da Vinci to relieve the commerce of Milan. He had not cheap steel, therefore could not use materials in tension. A good mechanic and engineer, understanding perfectly the qualities of masonry and timber, the ancient materials of construction, he used them so skillfully that his work could not be improved until modern progress gave us steam power and cheap steel and made possible structures depending on tensile strength. Engineers have attempted substitutes for Leonardo's lock, but with very moderate success. Edwin Clark, of England, built balanced hydraulic lifts, suitable for small single boats, where the foundation could be rock, and the German government has recently built a lock operated by four huge screws at the corners, assisted by a float. But locks of these types are inherently defective and involve the risk of dislocating the transportation system and the exchange of commodities, which in our modern civilization would cause business paralysis, ruin and starvation.

These attempted structures have required delicate manipulation, exact regulation of the canal levels, and

Third: Absolute immunity from falling. The pneumatic lock falls up, if it falls at all. It is pressed up firmly against the anchors with an effort much greater than the weight of the lock and its load. If the anchors yield, the lock is forced up to a height such that the air in the air chamber is expanded to equilibrium with the load, and a volume of water equal in weight to the difference between the load and its initial excess of buoyancy has entered the air chamber.

Fourth: Water trap valve for controlling the air conduit.

Fifth: The powerful automatic leveling or synchronizing shafts, of construction cheap, and such that the price per pound does not increase with increased power.

Sixth: Dispensing with the dry dock and operating the lock directly in the lower level of the canal in a pit, the pit in which the lock works being part of the lower level.

Seventh: The substitution of steel, mainly in tension, for masonry. A thin steel plate will do more work than the heavy masonry walls of the Leonardo locks. In most situations the pneumatic lock requires masonry only to support the guides and as weights for the anchorages.

Eighth: Substitution of elastic resistance for mere stability due to dead weight, which reduces the strains due to shocks so that they can be taken care of economically.

The principal elements are:

1. The locks, which are identical structures, in balance, each having a lower open-bottomed air chamber on which it floats and an upper gated lock chamber,

There is an interlocking apparatus or sequence machine which prevents doing the wrong thing at the right time while working the locks and a governor which keeps the locks from running away and stops them at the right elevation.

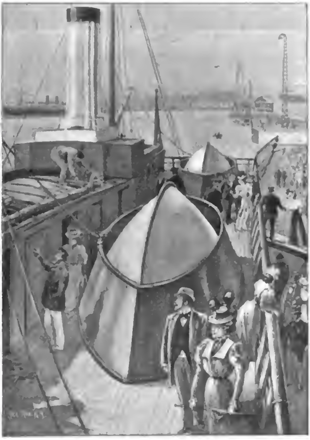
It is obviously impossible to exactly balance any load, especially a variable load, upon an unstable medium, such as air. It was, therefore, necessary to do one of two things; either

a, to make the lock deficient in buoyancy and provide a rigid auxiliary support, or

b, to make the lock superbuoyant and restrain it from rising too high by the engagement of the lock structure with anchors.

The latter was adopted after many designs of the first type had been considered and found defective. The elevated lock is firmly held and thrust upward against the anchors, which restrain it, with a surplus buoyancy or lift exceeding any possible variation in load or buoyancy. The air pressure in the elevated lock is great enough to expel from the air chamber a weight of water 25 to 30 per cent. greater than the weight of the loaded lock, the upward strain being held by anchors before referred to. This constant working pressure is maintained by a pneumatic accumulator, which is a cylindrical tank, movable vertically and weighted to give the desired working pressure, and which is connected with the elevated lock and has sufficient volume to provide for such leaks as may occur and for changes in the density and temperature of the adjacent atmosphere. The depressed lock floats as a pontoon and requires no care.

The machinery connected with the locks, besides the



VIEW OF THE DECK.

VIEW OF THE BOWS.

ON WHEELS ACROSS THE SEA—THE NEW ROLLER STEAMBOAT ERNEST BAZIN.

required the maintenance of dry docks in the lower level big enough to contain the locks and their appurtenances, which land therein when they descend.

A lock is the heaviest of engineering structures, carries per square foot a load greater than the load per running foot of the heaviest railroad bridge, and is subject to tremendous and cumulative distorting forces. Therefore, a lock structure must be of simple type and extreme power, and automatically guided and controlled by apparatus strong enough to, beyond peradventure, arrest distorting forces in their incipiency.

Locks and aqueducts are liable to be rammed by boats. In old fashioned structures either the structure or the vessel must be wrecked. A steel structure properly designed can cushion a blow so that it will be harmless.

The work done in perfecting the pneumatic lock may be briefly described as follows:

First: The substitution of compressed air for water as the support of the locks and vessels. Increasing the height of the air column does not increase the pressure, and therefore high lifts are operated with the same pressure which operates low lifts.

Second: The use of low pressures in lieu of high pressures, the air pressure being very little greater than that due to a column of water in height equal to the draught of the locks. The working pressure in the lock with 12 feet draught is 8 pounds per square inch; with 30 feet draught, 16 pounds.

containing the water for floating the boats, and working in a pit formed in the lower level.

2. A valve-controlled air conduit system, for transferring air from one lock to the other.

3. Anchorages to restrain the superbuoyant elevated lock, these being built integral with—

4. Guiding structures to prevent the locks from tilting sidewise.

5. Automatic parallel motion, or synchronizing apparatus, to keep them from pitching endwise.

The locking members are built of steel, and each like a long gas tank, with a gated lock built on top of it.

The gates move about a center, like a locomotive throttle valve, and when open lie back in pockets at the side of the lock, and have buffers or cushions which elastically cushion the blows of the boat.

The air conduits extend from the air chamber of one lock to that of its mate, and have a U bend which makes a valve like a sewer trap. When the trap is full of water the air conduit is closed, and when the water is drained out of the trap air can pass from one lock to the other. There are side guides to keep the locks from tipping over sidewise and automatic levelers to keep them from pitching endwise. This automatic leveling apparatus consists in racks built on the moving lock, fixed racks built parallel thereto on the piers, and shafts along the sides of the locks and carrying pinions which mesh with the racks on the locks and the parallel fixed racks. As the locks move, the shafts and pinions roll between the fixed racks and the lock racks with which they mesh.

interlocker and governor, are hydraulic stops or cushions, which stop the lock gradually to prevent shock, a hydraulic accumulator and pump, an air compressor to supply leakage and to transmit power to the gate-opening engines, the capstans which pull the boats in and out, and to the interlocking machine and valves.

The operation of the locks is as follows: The moving power is a surcharge of water in the elevated lock, containing, say, a foot greater draught than the depressed lock. If the boats enter or if they be left out it makes no difference in the weight, and when the gates are closed the locks are ready to be translated. If then the water be drained out of the big trap valve, the excess of weight in the elevated lock will cause the air to flow into the lighter depressed lock, which will ascend, and the heavier elevated lock will descend; the machine being controlled by the side guides which keep the locks from tipping sidewise, and by the synchronizing shafts and gearing, which keep them from pitching endwise and maintain them perfectly level and true; the motion being practically frictionless or attended only by rolling friction. As the surcharged lock approaches the lower level it automatically takes on an additional load of water, inducing a great increase in the compressed air charge, which increase, transmitted through the open conduit to the elevated lock, thrusts it firmly up against its anchors with a buoyancy, say, one-fourth to one-third greater than the weight of the lock and its load. The main air conduit trap valve is then shut by filling it with water, and the air chamber of the elevated lock is connected with the loaded air tank or pneu-

* Abstract of lecture before the Franklin Institute, November 12, 1897.

matic accumulator, which automatically compensates for variations in the temperature or density of the adjacent atmosphere and also supplies such small leakage as is unavoidable. The gates of the depressed lock are then opened, and its buoyancy is increased so that it will float with just the desired depth of water with which it should rise.

The joint is then made between the elevated lock and the aqueduct face, and the space between the adjacent gates in lock and aqueduct is filled with water and the gates opened. The boat which has been raised is then swelled out into the aqueduct, or upper level, and the boat which is to descend is swelled into the lock, which at the same time is lowered and takes on the surcharge or greater draught of water which is the moving power of the system.

The distorting or destructive forces which are provided against are:

1. Shocks and blows due to bumping or ramming by the boats.

2. Sinking of the boats in one end or one side of the locks, producing uneven loading and tendency of the boat to tilt sidewise and pitch endwise.

3. Wind pressure.

4. Variations in the density and temperature of the adjacent atmosphere.

Provision is also made for raising the locks out of the water, so that they can be painted and repaired.

This invention substitutes steel for masonry and timber in lock structures, and renders feasible the building of canals with long levels and very high lift locks, few in number, and causing a little detention. Therefore it renders canals practicable in dry countries and over mountain ranges.

These locks give the engineer great freedom in planning his canal levels, and do away with the waste of water, as the canal bottom can be put down low enough to provide draught at the lowest water, and the banks carried high enough to hold the highest water.

BRIGG'S BICYCLE ATTACHMENT.

In the accompanying illustration is shown attached to a safety bicycle a secondary handle bar, with merits and demerits which are obvious. The ideas which the inventor, Mr. Brigg, of Harley Street, London, W., has set himself to carry out are based upon perfectly sound physical and mechanical principles, as regards rest for

the back of the rider and increased purchase for hill climbing and back pedaling. As will be seen, the inventor fixes to the top bar of the frame of the bicycle a secondary handle bar, which is vertically rigid, but is connected to the ordinary handle bar by a spring for steering. This auxiliary bar is provided as a means of rest for the muscles of the back when riding easily on the level, but for hill climbing greater effort can be exerted on the pedals by using it as a fulcrum, in which case the rider, holding the front bar in the usual way and pressing up against the auxiliary bar with the arms, is enabled to put additional pressure upon the pedals. Such are the advantages derivable from this duplicate attachment, but whether they compensate for the increase of weight or are sufficient to alter a fashion in the shape of bicycles now fairly matured it is not our intention to comment.—The Engineer.

THE DE LAVAL STEAM BOILER.

A few years ago, in presenting the de Laval steam turbine to the Society of Civil Engineers of France, we concluded with the following words: "The de Laval turbine cannot at present, with the ordinary pressures of steam, consume more than 7·3 kg. of the latter per effective h. p. and per hour.

"With higher pressures, a still greater reduction in the consumption will be obtained, and this is the great future of these machines.

"We are far from the limit that generators will be able to reach. They operated at the outset at a pressure of 2 kg. and even at the pressure of the atmosphere. A pressure of 4 kg. was considered as dangerous. But pressures of 6, 10 and 15 kg. have been progressively reached, and there is no reason why one of 30 kg. or more may not some day be attained.

"Now, piston motors are incapable of running at such pressures, while the de Laval turbine will be able to utilize steam perfectly at any pressure whatever, since the latter is converted into live force before entering the motor itself.

"A more precise examination of the question gives an idea of the great saving that may be obtained from high pressures with the de Laval turbine."

Our previsions of that time are now realized and even exceeded. What was our desideratum at that moment is now a reality.

The same ingenious inventor who devised the first steam turbine has just brought out a boiler capable of furnishing steam at 220 atmospheres.

What particularly characterizes M. de Laval's boiler, aside from its high pressure, is its automatic operation and regulation. In fact, the feeding with coal, water and air and the regulating of the steam production are done by the apparatus itself.

The steam generator, properly so called, consists of a continuous tube, through one extremity of which the water is injected, while the steam escapes from the other.

The vaporizing tube is of cylindrical section and of from 25 to 30 mm. internal diameter, and forms a series of concentric spirals around a conduit through which

creasing strength, it closes in succession the apertures that allow the steam to pass to the ajutages.

The following operations take place automatically: The coal descends upon the grate and is carried along by its rotary motion; the apparatus, K, under the action of the steam, causes the operation of the registers, a_4, a_8 and a_6, which allow of the passage of the air introduced by the blower driven by the turbine; and the feed pump, G, is actuated by the turbine, as is also a centrifugal pump coupled directly with one of the driving shafts and supplying the condenser, B.

As soon as the machine is charged, its regulator

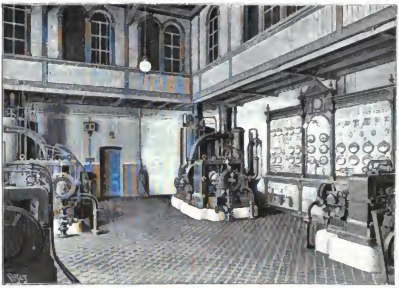


FIG. 1.—A DE LAVAL BOILER AND TURBINE AND A DYNAMO IN THE ENGINE ROOM OF THE JERLA WORKS, NEAR STOCKHOLM.

the coal is introduced. The whole is comprised in the annular space of an iron plate cylinder lined with heat-proof materials.

Below the conduit under consideration there is an arrangement which facilitates the continuous renewal of the coal and the cleaning of the grate. In the interior of a revolving grate, in the form of a truncated cone, there moves with a different velocity a cone of refractory bricks that carries along the fuel. Between the grate and the coal there is a loop in the water tube that performs the part of a scraper and keeps the grate constantly clean.

The boiler is provided with apparatus for regulating the supply of water and the admission of air into the furnace. The operation of these apparatus is based upon the action of balanced pistons by the pressure of the steam on one side and of the water under pressure and of springs on the other.

Fig. 2 gives a diagram of a complete installation of the boiler, turbine, condenser and accessory apparatus. The coal, which is introduced at the top, falls upon the cone, a_7, and fills the conduit, a_6, which is afterward closed. The reservoir, b_4, as well as a portion of the spiral, is filled with water.

As soon as the fire is lighted, the steam begins to be disengaged at a_4, and, through the regulators, D, and

opens the apparatus, E, slightly, the water loses some of its pressure, and the pistons of the apparatus, D, move in the contrary direction in allowing of the passage of a quantity of steam sufficient for the work required from the turbine.

The steam under a pressure capable of reaching 220 atmospheres (corresponding to 375° C.) enters the ajutages and completely expands therein up to the pressure of the condenser before being projected against the paddles of the turbine. After effecting its work, it goes to the surface condenser, B, whence, after condensation, it is forced by the pump, F, into the reservoir, b_4, and is thence taken up by the feed pump, G, and forced into the steam generating tube.

The centrifugal pump keyed upon one of the auxiliary shafts of the turbine furnishes water under pressure to a sort of ejector, b_5, which communicates with the space, b_1, where the steam condenses and thus carries along the air that may chance to exist therein. After passing through the ejector, this water is directed into the condenser upwardly, and thence flows to the exterior. The centrifugal pump thus performs the office of both a circulating and air pump.

The apparatus, H, branched upon the conduit of the feed pump, in which there prevails a pressure higher than that of the steam in the generator, constantly

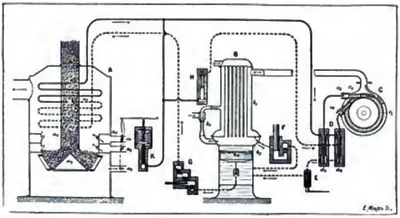

FIG. 2.—DIAGRAM OF A DE LAVAL BOILER.

A, the boiler; B, the condenser; C, the turbine; D, the steam regulator; E, the water pressure regulator; F, pump of the condenser; G, feed pump; H, apparatus for balancing the pressure of the steam and of the water circulating in the regulator, D

the ajutages, e_1, e_2, e_3 and e_4, enters the turbine, C, which revolves with greater and greater velocity in measure as the pressure increases.

The apparatus, E, which was completely open, and in which the water coming from the feed pump, G, through the intermedium of the apparatus, H, circulated freely, begins to close through the action of the regulator and turbine. The pressure of this water, thus intercepted, progressively increases in the apparatus, D. In adding itself to the action of the springs, which are of unequal and progressively de-

balances the pressure of the water that circulates in the regulator, D, with the pressure of such steam and thus prevents the regulator from being always closed to the passage of the latter.

The blower, which is keyed upon one of the auxiliary shafts of the turbine, furnishes the quantity of air necessary for the combustion and produces the draught. The regulator, K, regulates both the action and the discharge of the steam, now opening and now closing the registers, a_4 and a_5, according to the pressure of the steam and the charge of the machine.

Lastly, it is capable, while closing the registers, a₃ and a₄, of opening the register, a₁, and of thus blowing fresh air upon the spirals themselves so as to arrest the production of steam.

The boiler is capable of vaporizing from 35 to 40 liters of water per square meter of vaporizing surface and of furnishing from 7·5 to 8 kg. of steam at from 100 to 220 atmospheres per kilogramme of coal.

Among the principal advantages of the new boiler may be mentioned its simplicity, its lightness, the little space that it requires, the ease with which it may be installed and operated, the rapidity with which it is set in operation, its production of dry and superheated steam, etc.

The electric lighting of the Universal Exposition at Stockholm this year is assured by the de Laval turbines and high pressure boilers. The electric plant comprises four groups of 100 h. p. and two of 50 h. p. Each group is composed of one turbine, one dynamo turbine and one condenser, as well as the accessory apparatus for feeding and regulating actuated by the turbine.

The steam turbine manufactory at Jerla, near Stock-

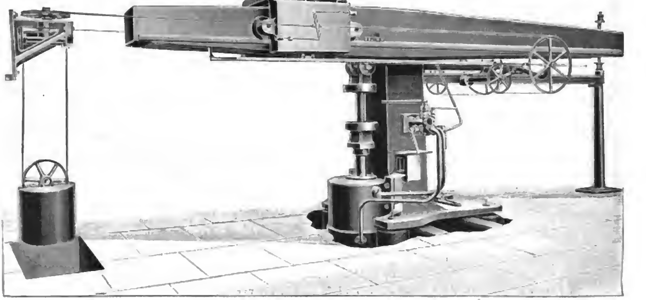
Grate area....	2·51 sq. m.	(27 sq. ft.)
Wheel base, fixed maximum	2,600 mm.	(8 ft. 9·5 in.)
" " total..........	6,460 mm.	(21 ft. 2 in.)
Feed water, in tanks.	4 cubic meters	(880 gal.)
" " in boiler.......	3·8 "	(836 ")
" " total capacity,	7·8 "	(1,716 ")
Fuel	1·5 "	(53 cub. ft.)
Weight, empty...	55 tons.	
" in running order..	69·9 "	
Axle load, maximum	14 "	
Gage.....	1,435 mm.	(56·5 in.)

The engines have especially been constructed for pulling heavy trains on the steep gradient of 1:50 and 1:30 of some Thuringian mountain lines of the Prussian state railways, Probstzella-Wallendorf, Schwarzathal, Triptis-Blankenstein and Ploen-Ritschenhausen. The special conditions refer to gradients of 7·5 kilometers (4½ miles) lengths and various minimum curves. On gradients of 1:30 and curves of 180 meters (590 ft.) trains of 250 tons were to ascend at a speed of 15 kilometers (9·3 miles), 110 tons were to ascend at a speed of 30 kilometers (18·6 miles); on gradients of 1:40 and curves of

object aimed at has fully been attained, for on gradients of 1:40 with curves of 200 meters (656 ft.) radius, trains of 296 tons have been pulled with a speed of from 17 to 20 kilometers (10·6 to 12·4 miles), and trains of 330 tons with a speed of 13 kilometers (8 miles); and on gradients 12·5 kilometers (7¾ miles) in length, of 1:50 with curves of 320 meters (1,050 ft.) radius, the required speed of 15 kilometers (9·3 miles) has been maintained with trains of 300 tons. The specified conditions have hence been more than fulfilled. The engines are said to move very smoothly, owing chiefly to the particular construction of the framing, which is not rigid, but linked, enabling the locomotive to take all curves easily and to adapt itself to irregularities in the track, without impairing the adhesion.—Engineering.

ONE HUNDRED TON TESTING MACHINE.

THE fine machine illustrated herewith was made by Messrs. J. Buckton & Company, of Leeds, for the Dowlais-Cardiff Works, where it is now in use. It is constructed under the Buckton and Wicksteed's patent, and is actuated throughout by hydraulic pressure



ONE HUNDRED TON TESTING MACHINE.

holm, is likewise run exclusively by these new boilers. In Fig. 1 is given an internal view of this station. To the right of the engraving may be seen a group of apparatus consisting of a boiler, a dynamo turbine, a condenser and various accessories.—K. Sosnowski, in La Nature.

THE HAGANS COUPLED LOCOMOTIVE.

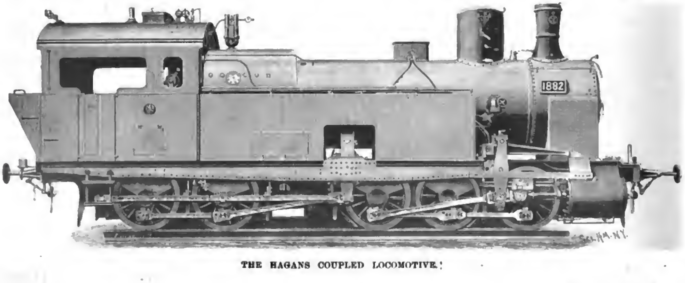
WE illustrate herewith a locomotive built by the locomotive works of Henschel and Sohn, Cassel. The Prussian State Railway Department had originally ordered two of these engines; several more have already been added. Of the five coupled axles of these locomotives three have their bearings in the main frame, the other two in the bogie frame; the coupling is as described on the occasion referred to. The chief dimensions of this locomotive, which can pass over normal (1,435 millimeters) gage lines with curves of 180 meters (590 feet) radius, are:

Cylinders, in diameter	520 mm.	(20·48 in.)
" stroke	630 "	(24·8 ")
Wheels, diameter	1,200 "	(47·2 ")
Steam pressure.......	12 atmos.	(175 lb.)
Heating surface, direct	8·16 sq. m.	(87·84 sq. ft.)
" " indirect..	129·05 sq. m.	(1,389 sq. ft.)
" " total......	137·21 sq. m.	(1,476·8 sq. ft.)

200 meters (656 ft.) the speeds were to be 15 kilometers (9·3 miles) for 270 tons and 30 kilometers (18·6 miles) for 100 tons; on gradients of 1:50 of 7¾ miles length and curves of 350 meters (1,148 ft.), speed of 15 kilometers (9·3 miles) was to be maintained for trains of 330 tons. For the calculations, coefficients of 0·18 (start) and 0·15 (run) were to be adopted for the friction between wheels and rails. The capacity for coal, 6 cubic meters (212 cubic feet) and for water, 7 cubic meters (1 544 gallons), were to suffice for runs of 20 kilometers (12·5 miles).

The load on each axle was not to exceed 17 tons, grate area and heating surface could not be dimensioned as in ordinary usage, but the designers have availed themselves of an expedient to which engine drivers resort in cases of forced runs, that is, to keep plenty of water in the boiler. The boiler has a diameter of 1,600 millimeters (63 in.), is raised a little above the firebox, and the firebox is made so low that it does not project more than 76 millimeters (3 in.) above the middle of the boiler. By these means the water level can be varied by 400 millimeters (16 in.); the boiler is, therefore, for all purposes, very spacious, and can carry 3·8 cubic meters (836 gallons) above lowest water level. The remaining 4 cubic meters of water are kept in a lateral tank; in these 3·8 cubic meters of heated water are stored up so that the engine can rapidly get up plenty of steam when arrived at the foot of a steep gradient. The

brought from the works' accumulator. The straining piston will put on a pull up to 100 tons at any desired speed, the speed being regulated by a hand lever on the hydraulic valve. Another valve admits the hydraulic pressure to a horizontal ram which actuates the traveling poise weight, which can be advanced along the steelyard at any desired speed by regulating the hydraulic valve. The result of this arrangement is that strong samples of plates up to 3 in. area in cross section can be tested with perfect accuracy as to their ultimate strength and total extension at the rate of sixty pieces per hour, and a record has been reached with lighter pieces of 120 in the hour. The gear which transmits the power from the horizontal hydraulic ram to the poise weight is so connected to the poise as to apply the force strictly in a horizontal direction, and to be incapable of supporting any part of the poise weight, or influencing in any way the sensibility in the oscillations of the steelyard. The machine is extremely massive, and the principle which enables such rapid testing to be delicately conducted is that of employing a very heavy poise weight with a very low velocity of oscillation. The steelyard is of the double armed type, invented by Mr. Wicksteed. The poise weight when at zero is at the end of the negative arm. In this position it is balancing an equal weight on the long arm or positive end of the steelyard, the result being that with

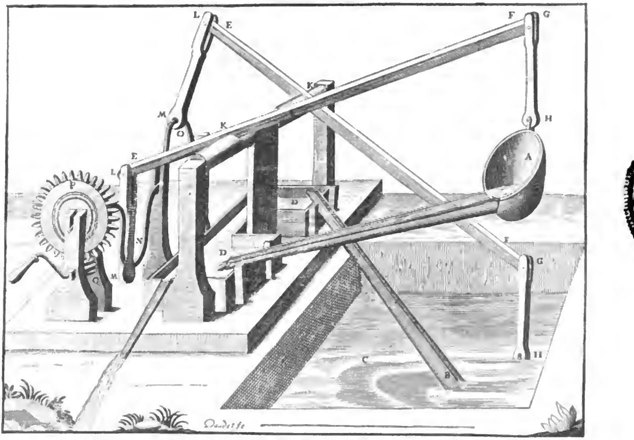


THE HAGANS COUPLED LOCOMOTIVE.

a 30 ... poise a total weight of three tons is utiliz... in measuring the strength of the sample, and the velocity ratio between the end of the steelyard and the testing shackle is only 33 to 1. The accuracy of the machine is guaranteed to 1 in 5,000, and although the steelyard and poise weigh together about four tons, yet they offer such small inertia resistance that the strength of sewing cotton can be measured on this machine with as much accuracy as with dust shot in a scale pan. The arrangements for returning the poise weight and the straining piston will be readily understood from the illustration. We are indebted to The Engineer for the engraving and article.

MACHINE FOR DRYING UP A MARSH OR FOR DRAWING WATER FROM A SHALLOW PLACE.

THE large bowls, A, B, which are to draw water from the reservoir, C, and raise it to the reservoir, D, are attached, through the extremity of their gutter, to iron pins moving upon the edge of the reservoir, D. They are suspended by the levers, E, F, at their end, F, through a forked link, G, H, and these levers, whose center of motion is at K, are drawn at their extremity, E, by two other links, L, M. These two last links being attached through an eye to the two cranks, N, O, of the wheel, P, raise and lower the levers, E, F, and consequently the bowls, A, B, when the wheel, P, revolves.



MACHINE FOR DRYING UP A MARSH OR FOR DRAWING WATER FROM A SHALLOW PLACE.

This latter is actuated by hand through a winch that one places at the end of the axle of lantern wheel, Q.—From Recueil d'Ouvrages Curieux de Mathematique et de Mécanique, 1733.

LOCOMOTIVES FOR JUNGFRAU RAILWAY.

THE Jungfraubergbahnelectromotive is said to be the most powerful cogwheel locomotive which has ever been constructed, and it will be granted that it has the advantage, if that is anything, of a very long name. It is being built by Messrs. Brown & Boveri, of Baden, for working the trains on the gradients of the Jungfrau; and as it is of peculiar design, unlike anything of the kind on any other mountain railway, we give a few particulars which we extract from the description appearing in a Swiss contemporary. As its name implies, it is driven by electricity, through the trolley, and the motors are contained within a passenger car. This combination of engine and car gives great weight on the driving wheels; and the cogwheels, by which adhesion is obtained, are the less likely to rise out of the rack, which extends the whole length of the line between the rails.

The frame of the car contains, between the two supporting axles, the two driving axles, on which are the cogwheels. Two electromotors, each of 125 h. p. at 800 revolutions, drive, by means of double reduction gearing, the main cogwheel. The highest output of these motors will be 300 h. p., corresponding to about 285 apparent kilowatts, or about 235 amperes per phase, at a pressure of 500 volts. The gear pinions are of aluminum bronze, the large spur wheels and the driving cogwheels of cast steel. The latter are made as large as possible, in order to have a good grip of the teeth in the rack and as little wear from friction as possible. It is important that a mountain locomotive should be well provided with brakes, and this has three different varieties—an electric brake on the motor shaft available while there is current passing through the motors; a hand brake which acts upon the driving gear; and a third set which acts by gripping the rails, and which is under the control of the conductor as well as the driver. Everything has been done to secure safety and efficiency.

TYPE WRITER RIBBONS.

By ISIDOR FURST.

THE ever recurring query as to reinking type writer ribbons has been kindly referred to me by the editors of this journal.

In treating of this question the second time, I shall endeavor to put whatever knowledge I possess regarding it into such form as will enable any person of average skill to make an ink suitable for any particular style of ribbon and apply it. I mean to illustrate the principles involved and how to meet the various requirements. My reason for doing this, rather than to give a specific formula to be followed in every instance, is that often an experimenter has already produced an ink which lacks only some correction to make it entirely suitable, for "there are many ways leading to Rome." Besides, an ink which may have been suitable at one time may fail at another, under different conditions, and once a person knows how to correct a defect, the ink may be made to answer all purposes.

The constituents of an ink for type writer ribbons may be broadly divided into four elements: 1, the pigment; 2, the vehicle; 3, the corrigent; 4, the solvent. The elements will differ with the kind of ink desired, whether permanent or copying.

Permanent (Record) Ink.—Any finely divided, nonfading color may be used as the pigment, vaseline is the best vehicle, and wax the corrigent. In order to make the ribbon last a long time with one inking, as much pigment as feasible should be used. Suppose we wish to make black record ink. Take some vaseline, melt it on a slow fire or water bath, and incorporate by constant stirring as much lampblack as it will take up without becoming granular. Take from the fire and allow it to cool. The ink is now practically finished, except, if not entirely suitable on trial, it may be improved by adding the corrigent wax in small quantity. The ribbon should be charged with a very thin, evenly divided amount of ink. Hence the necessity of a solvent—in this instance a mixture of equal parts of petroleum benzine and rectified spirit of turpentine. In this mixture dissolve a sufficient amount of the solid ink by vigorous agitation to make a thin paint. Try your ink on one extremity of the ribbon; if too soft, add a little wax to make it harder; if too pale, add more coloring matter; if too hard, add more vaseline. If carefully applied to the ribbon, and the excess brushed off, the result will be satisfactory.

On the same principle, other colors may be made into ink; but for delicate colors, albolene and bleached wax should be the vehicle and corrigent, respectively.

The various printing inks may be used if properly corrected. They require the addition of vaseline to make them non-drying on the ribbon, and of some wax if found too soft. Where printing inks are available, they will be found to give excellent results if thus modified, as the pigment is well milled and finely divided. Even black cosmetic may be made to answer, by the addition of some lampblack to the solution in the mixture of benzine and turpentine.

After thus having explained the principles underlying the manufacture of permanent inks, I can pass more rapidly over the subject of copying inks, which is governed by the same general rules. Personally I am not in favor of the use of copying ink: first, because the print is liable to fade, smear and become invisible; second, because it is unsuitable for legal and other documents of value; third, because it is easier to write two or more copies at one operation with manifold (carbon) paper than to make a second press copy after the writing is done.

For copying inks, aniline colors form the pigment; a mixture of about three parts of water and one part of glycerine, the vehicle; transparent soap (about one-fourth part), the corrigent; stronger alcohol (U. S. P.) (about six parts), the solvent. The desired aniline color will easily dissolve in the hot vehicle, soap will give the ink the necessary body and counteract the hygroscopic tendency of the glycerine, and in the stronger alcohol the ink will readily dissolve, so that it can be applied in a finely divided state to the ribbon, where the evaporation of the alcohol will leave it in a thin film. There is little more to add. After your ink is made and tried—if too soft, add a little more soap; if too hard, a little more glycerine; if too pale, a little more pigment. Probably printer's copying ink can be utilized here likewise, because everyone now has the means to modify and correct it to make it answer the purpose. I have not tried it, because I am opposed to copying inks.

Users of the type writer should so set a fresh ribbon as to start at the edge nearest the operator, allowing it to run back and forth with the same adjustment until exhausted along that strip; then shift the ribbon forward the width of one letter, running until exhausted, and so on. Finally, when the whole ribbon is exhausted, the color will have been equably used up, and on reinking, the work will appear even in color, while it will look patchy if some of the old ink has been left here and there and fresh ink applied over it.

According to the directions here given, I have done nearly all the reinking of my ribbons for more than seven years, and I am sure, if the reader should fail, it will be due to inattention on his part to some of the principles laid down.

We are indebted to the American Druggist for the above particulars.

HISTORY OF TINFOIL.

TINFOIL was invented early in the fifties by John J. Crooke, a young man connected with the drug and chemical trade of New York. Crooke's inventive tendencies led him outside of his regular business, and he endeavored to perfect a method of coating iron bolts with copper, as a substitute for the copper bolts which he saw being used in shipbuilding. In this he was unsuccessful; but it is stated that the experiments led him up to the combining of other metals, and he devised the plan of rolling tin upon lead sheets, producing a sort of weld between the two. Before this the only tinfoil known was pure tin beaten out into sheets as gold leaf is.

A patent was obtained on the invention, and the production of the material was begun at Nos. 355-7 Stanton Street, New York, some pure tinfoil being also made. A business card of this establishment has been preserved, which bears the inscription: "Foil Rolling Mill and Metallic Cap Works; tobacconists'

foil, plain or embossed, tin sheet foil for druggists and bottles, superior to imported article."

The new foil was first used for the wrapping of fine cut tobacco, which had previously been wrapped in paper only. Its advantages for this purpose were obvious, including its sightly appearance and its property of keeping the tobacco moist.

The printing or stamping of names and designs upon the foil was a speedy outgrowth of its manufacture, which was stimulated, after the imposition of internal revenue in war times, by the printing of the internal revenue stamp directly upon the tobacco wrappers. A contract for this work was obtained by Mr. Crooke from the government after many complaints of fraud and loss to the revenue through difficulties connected with the use of paper stamps.

Vast quantities of the foil are used for the packing of domestic Limburger cheese, the material being sent to the Northwestern States for that purpose by the car load. The wrapping of cigarettes in tinfoil is a comparatively new development, the importance of which is manifest when the extent of cigarette manufacture is considered. About one-half of the output of the Crooke factory is rolled pure tin, as the proprietors always boast that only this shall be used when the foil wrapping is to be directly in contact with food. Large amounts are taken for the packing of yeast cakes and also for fancy cheese and other food products of the "delicatessen" order. A great demand for the pure tin comes from the manufacturers of plug tobacco, who use it for the wrapping of the separate plugs and also in sheets between layers of the tobacco. When a machine for packing tobacco was invented, which required tinfoil and paper to be fed into it altogether, a process was devised by which the foil was furnished already backed with thin paper and firmly adhering to it. The pure tin, by the way, is not used for the Limburger cheese wrappings, but the foil of tin and lead, as there is an inner wrapper of paper. Besides, it is probably thought that nothing could hurt Limburger anyway.

The embossing of the foil in various ornamental designs is a branch of the business which has gradually developed until now highly artistic results are obtained. In the fancy patterns, the silvery surface is diversified in bright and "dead" effects, by stars, plaids, flowers, bars, diagonals, lines, etc. Many samples are printed in colors, such as pink, blue and red, both the colors and the patterns being produced by putting the sheets of foil through a process of regular cylinder printing. Other specimens are lacquered with gold and embossed in various forms, presenting a beautiful appearance, and still others are brilliantly lacquered in colors. Confectioners, druggists, cigar manufacturers and cigar box makers use quantities of these fancy designs, many of which are specially made for particular firms and serve as a sort of trade mark. The thickness, or rather the thinness, of the foil runs from 0·0005" upward, the thinnest being the most expensive, as representing the most labor. It is rolled in sheets, which on the average are 50' long and 5¼" wide (some also being rolled as wide as 12"), and is then cut into the lengths desired.

The makers of bottle caps are not classed with the tinfoil manufacturers, as these caps are not made of the regular foil, but are spun on a lathe from a mixture of lead and tin. Besides the John J. Crooke Company there are now four tinfoil factories in this country, two in New York, one in Philadelphia, and one in St. Louis. These four were started after the expiration of the original Crooke patent. The foil is also made in England, France and Germany, its production being especially large in the last named country. Owing to the impossibility of competing with foreign labor in its manufacture, the United States has no export trade in the article, except a little to Havana, where it is used in the packing of cigars.

The output of tinfoil in this country amounts to millions of pounds a year, but there are no data accessible on which to base exact or even approximate figures. The market price of the most expensive embossed and lacquered foils runs as high as 75 cents a pound, and from that it goes down so low that manufacturers do not care to quote the minimum rates. It is said that the average price has been reduced one-half within the last fifteen or twenty years, being lower now than ever before since the foil was invented. This was due to increased facilities of manufacture, increased production, and, especially, keen competition, particularly in the lower grades of the product.

There is constant improvement in the machinery and processes of tinfoil making and also in the article turned out. New uses for it are discovered yearly. Its chief merits as a wrapping are its pleasing appearance, its adaptability to ornamentation, its keeping in place as paper, and above all, its preservation of the contents from drying.—Tin and Terne.

HOT SODA WATER FOUNTAIN FOOD PREPARATIONS.

Bouillon.

Extract beef .... 3 ounces.
Water .... 2 pints.
Corn starch .... 1½ ounces.
Salt .... 2 "

Boil the corn starch with the water until the starch is thoroughly cooked; then add the extract of beef dissolved in 8 ounces of hot water; add the salt, and when dissolved make the finished product measure 2½ pints. To draw this use about 1 ounce to a 8 ounce mug and flavor with a few drops of a flavoring essence composed of tincture of summer savory, 3 ounces, and tincture capsicum, 2 drachms.

Hot Tomato Bouillon.

Beef extract .... ½ to 1 teaspoonful.
Or
Liquid beef extract ..... about 1 fl. ounce.
Tomato catsup ..... about ½ "
Hot water, enough to fill an 8 ounce mug.
Season to taste.

Beef and Celery.

Liebig's extract of beef .... 8 ounces.
Hot water .... 1 pint.
Extract of celery .... 1 drachm.
Caramel .... 1 "

Mix beef in hot water, add celery and color, use a shaker top in the bottle, as there is a sediment in the beef extract which necessitates shaking. In a six or seven ounce cup shake about two teaspoonfuls of the beef extract prepared as above, draw on this sufficient hot water, add salt to suit taste, stir with a spoon, shake a little white pepper on top.

Hot Clam Shake.

Clam juice .... 2 ounces.
Hot milk .... 4 "

Shake well, add pepper and salt, stir well and serve.

Hot Clam Bouillon.

Clam juice .... 1 ounce.

Fill mug with hot soda, add pepper and salt, stir well and serve.

Hot Clam Broth.

Clam juice .... 1½ ounces.
Hot Milk .... 2 "

Fill mug with hot soda, add a sprinkle of salt and white pepper, stir well and serve.

Hot Ginger Clam Broth.

Powdered Jamaica ginger .... 1 teaspoonful.
Cream .... 1 ounce.
Clam bouillon .... 1 "
Butter, sufficient quantity.
Celery salt, sufficient quantity.

Fill mug with hot soda, stir well and serve.

Mock Turtle Extract.

Extract of beef .... 2 ounces.
Concentrated chicken .... 2 "
Clam juice .... 8 "
Hot water .... 3 pints.
Tincture of black pepper .... 1 ounce.
Essence of celery .... 3 drachms.
Essence of orange peel .... 1 "

Mix and dissolve thoroughly. To dispense.

Mock Turtle Bouillon.

Mock turtle extract .... 2 ounces.
Sweet cream .... ½ "

Stir while adding hot soda. Serve spices. (Bonham's Guide).—Pharmaceutical Era.

DISINFECTANT SOAPS.

MR. S. RIDEAL, D.Sc., scores a good point in his paper on this subject, read before the British Pharmaceutical Conference (Pharmaceutical Journal), and contending that although our knowledge of disinfectants has much increased, very little progress has been made with disinfectant soaps, many of those which have been in use for years having little germicidal power. Many valuable disinfectants are quite unfit for use in soaps.

The conditions under which a disinfectant soap acts are very different to an ordinary disinfectant. The time of contact is less, and also the volume of water, and the disinfectant to be effective must be readily soluble in water.

With essential oils and coal-tar products, although emulsified by the soap, their effect is uncertain in soaps, owing to the length of time necessary to produce the death of the most resisting of the organisms.

A base of oleate is preferable to one of stearate or palmitate, as sodium stearate or palmitate is thrown down by hot water (F. Krafft and A. Stern).

Some experiments are required on a basis consisting of soda and potash soaps mixed. Unna suggests that medicaments are more easily absorbed if the soap be superfatted, but for use with disinfectants an excess of alkali is preferable, as fats retard disinfectant properties. Lenti showed that fatty solutions are unsuitable bases for disinfectants. Dr. Breslauer has confirmed this, lanolin being the least objectionable as a basis. Oils and fats for ointments and soaps should be sterilized by heat, as they often contain germs. This is usually done in process of manufacture.

Soaps have considerable disinfectant power, and the action is more marked with cold than with hot water. Prolonged contact with soap renders surfaces practically sterile.

Acids and halogens are obviously unsuited for soaps. Hypochlorites are compatible to a certain extent.

Fluorides and silico-fluorides were found by Thompson to be strongly antiseptic, and they are compatible with soap.

Sulphur and alkaline sulphides blend well with soap, and are useful in skin diseases; but sulphur is slow in action on account of its insolubility. Alkaline sulphides are caustic, and recently ichthyol has been suggested. Most of these gradually evolve H_2S, and are not popular.

Boric acid would be converted into borate, and have little value.

Metallic salts, except Na and K, are precipitated in an insoluble form.

Oleates.—These have been proposed for soaps, but as the oleates of most metals are insoluble in water, it is a question how far an oxide or oleate can be used for washing. Zinc hydrate boiled with sodium to form sodium zincate as neutral as possible, incorporated with yellow soap, showed no sign of separation of insoluble oleate.

Manganese soap is said to be strongly siccative. It is made by decomposing manganese sulphate with soap.

Arsenical Soaps.—The small quantity of arsenic present is useless for antiseptic purposes, but in constant use might have some effect on the skin.

Mercury Soaps.—It is difficult to prevent the formation of mercuric oleate, which is insoluble and of little value. The double iodide of K and Hg has stronger germicidal powers than $HgCl_2$. It is easily incorporated with soap, and there is no separation when dissolved in warm water. The strength recommended is one-third of HgI_2 and one-third of KI in 100 of soap. It is said to be effective in the proportion of one part of HgI_2 in 4000 of water. A soap of this kind which is on the market contains more KI than is sufficient to form the double salt. Potassio mercuric iodide is compatible with strong alkalies, does not precipitate albumen, and is not easily reduced. The carbolate of mercury soap is not so powerful, and is slower in action. Dr. Rideal concludes that a metal in the form of an oleate is readily absorbed by the skin, and that oleate soap would be useful if an internal effect is required, but for local antiseptic or disinfectant purposes the metal must be presented in a soluble form to water, as in the zinc soap mentioned above, or mercuric iodide soap. This is the natural use for soap; the other action more properly belongs to the ointment.

Carbolic and Cresylic Soaps.—The odor of these soaps is an objection. A number of toilet soaps are advertised in conjunction with the names of disinfectants, but contain so small a quantity as to be quite useless as germicides.

Essential Oils.—The disinfectant powers of essential oil have been much overrated, and are often irritating when used in disinfecting quantities. When such ingredients are added to the "crutching pan," it is always necessary to neutralize the free alkali at this stage by the ammonium salt process, or to postpone the addition of the oils until after the operation of fitting. Volatile disinfectants, such as phenol, camphor, thymol, etc., suffer considerable loss if introduced in crutching in the ordinary manner, or added during remelting, so that the quantity present becomes uncertain. Such medicinal soaps should be milled or plotted. The cakes should be packed in tinfoil (mercury soaps in oiled paper or guttapercha tissue). It has been suggested to coat the surface of the cakes with gelatin.

In a series of experiments made in 1896, using two per cent. solutions and broth cultures at 37° C. of two representative organisms, Dr. Rideal found soap with oil of cloves to have little antiseptic action, scarcely exceeding that of curd soap. Carbolic soap (3 lb. per cwt.) was about the same. A series of experiments, not yet complete, shows at present the following results with B. coli communis and two per cent. solutions.

Curd soap, sterile between one and three hours.

Zinc soap (made as described in paper), alive after three hours.

Carbolic soap, sterile between one-quarter and one hour.

Coal tar soap, sterile between one quarter and one hour.

Sanitas soap, alive after three hours.

Terebene soap, alive after three hours.

The variations in these are due to the varying amount of water present.

IRON AND STEEL PRODUCTION IN FRANCE.

SOME official returns have just been issued regarding the metallurgical production in France during the first half of the current year, from which we compile the following few brief particulars. The returns show that the total output of pig iron in the country during that period amounted to 1,223,638 tons, or an increase of 77,044 tons over the first half of 1896. The production of forge pig is returned at 977,719 tons, as against 893,909 tons in the first six months of 1896, and of foundry pig 245,919 tons, as compared with 252,685 tons.

Meurthe-et-Moselle continues to be by far the leading French pig iron producing center, this district being responsible, during the first half of the current year, for 761,199 tons, as compared with 719,961 in 1896, or considerably more than half of the total output in the country.

The second principal district is the Nord, where the output of crude metal for the six months totaled 143,000 tons, while in the Gard the production increased from only 18,851 tons in the first six months of 1896 to 26,422 tons this year.

As regards the finished iron trade the output, as will be seen from the following table, has declined, as compared with the second half of last year, to the extent of 17,281 tons, although it is 14,030 tons better than was recorded in the first six months of 1896:

	Jan.-June. 1897. Tons.	July-Dec. 1896. Tons.	Jan.-June. 1896. Tons.
Iron bars	369,747	376,172	347,885
" rails	372	459	417
" plates and sheets	35,577	46,346	43,364
Total	405,696	422,977	391,666

In this branch the Nord continues to occupy the leading position, with 152,610 tons, as against 141,731 tons in the past six months of last year, followed by the Ardennes, where the production, however, increased but slightly from 47,012 tons in 1896 to 48,555 tons in 1897.

The steady progress in the steel trade has been well maintained, the production during the period under review showing, as given below, a satisfactory increase over both the two preceding half years:

	Jan.-June. 1897. Tons.	July-Dec. 1896. Tons.	Jan.-June. 1896. Tons.
Steel bars	270,952	283,020	218,042
" rails	95,426	82,286	88,389
" plates and sheets	108,440	105,666	106,105
Total	474,818	470,972	412,536

In both the Nord, the Meurthe-et-Moselle and the Saône-et-Loire districts the output of steel is undergoing a steady development. The Nord leads the list with 96,245 tons for the six months as compared with 71,548 tons in the first half of 1896, or an increase of roundly 24,000 tons, while in the Meurthe-et-Moselle the output totaled 61,747 tons, as against 56,943 tons.—Colliery Guardian.

One of the nicest ways to draw temper on a long, slender tool, like a stay bolt tap, is to use a piece of gas pipe. Run the pipe through the fire, making the fire long enough to accommodate it, and put in your tap, turning it and watching it, and you can get the nicest sort of heat. Some tool hardeners do their heating to harden in a pipe. Where much of this kind of work is to be done, the device can be improved, as, for instance, by the use of permanent supports for the pipe. Smiths are prolific in rigging up devices and can easily extend and elaborate the idea.—Sparks.

ELECTRICAL NOTES.

An isolated electric plant was recently installed in a large tea firing or curing establishment in Yokohama. This establishment employs 2,000 people, who clean and sort the tea by native fan blowing and sifting machinery, after which it is taken to the firing rooms, containing 1,500 pots, set in brick work and heated by a slow fire, the tea being stirred continuously by the coolie who attends each pot, the work going on day and night during the busy season.—Philadelphia Record.

At present there are in use in America from 150 to 200 miles of street railway track the joints of which have been all welded, either by the electrical or the "cast welding" system, so that the rails are actually continuous. As to the success of this system, the testimony is rather conflicting; but the fact appears to be that the difficulties encountered have been no more serious than might naturally be expected to accompany so novel a departure from usual practice. The cast welding system promises to supersede the electric welding system, says The Engineering News, because it produces as good or better results at a less cost. Unless some further trouble should develop, or those already found should prove more serious than they thus far have done, it seems quite probable that the street railway track of the future will have a continuous rail, at least wherever it is laid in paved streets.

The possibility of finding for aluminum a wide field of usefulness as an electric conductor has very frequently been discussed—not without hope on the part of the producers of the new metal—but there have not been sufficiently reliable data, the tests of the conductivity of aluminum as compared with copper showing a very low result. This, it has now been proved, is due to the fact that the aluminum tried had been impure, a small percentage of foreign element making a material difference. Some very careful tests have been made on behalf of one of the American technical institutes (the Franklin), and these show very favorable results. Thus aluminum with 1·5 per cent. of impurities was found to have little more than one-half of the conductivity of copper, or 55 per cent.; while, when the impurities were reduced to 1 per cent., the conductivity increased to 59 per cent. that of copper; with ½ or 0·5 per cent. of impurities the conductivity became 61 per cent.; and with absolutely pure aluminum it was found that copper was only one-third more powerful as a conductor, or that it was a case of 67 for aluminum against 100 for copper. The question therefore arises as to whether pure aluminum can be produced 33 per cent. more cheaply than copper of the same capacity. There seems every reason to believe that it can be. The same research committee found that the conductivity of hard drawn commercial aluminum was nearly 1 per cent. higher when annealed.

An interesting paper by Trabert, on the crackling of the telephone on the Sonnblick, appears in the fourth report of the Sonnblick Verein. The Sonnblick, it may be stated, is one of the best known mountain observatories in the world, by reason of its height (10,154 feet), and especially by reason of the valuable results which have been derived by Hann and others from the observations there made. For six years, says Science, five observations a day have been made of the intensity of the crackling in the telephone at the summit. It appears from these data that in December the minimum crackling is at noon, with the maximum at 9 P. M., and a secondary maximum at 7 A. M., while in June there is a steady increase in the intensity of the noise from 7 A. M. to 9 P. M., without a noon minimum. The other months of winter and summer follow respectively the same rule as December and June, while the intermediate months, as expected, present the intermediate conditions. Further, the noise is greater in summer than in winter. Regarding the explanation of these phenomena, the author finds it chiefly in the presence of atmospheric electricity in the clouds over the Sonnblick, for there is a very striking correspondence between the crackling and the cloudiness on the summit, not only in the diurnal period, but in the annual as well. The days on which there is the greatest intensity of crackling are almost invariably distinguished by cloudiness, rain, snow or thunderstorms. The part played by earth currents must not be overlooked, for on one cloudless anticyclonic day there was a very well marked crackling, which could not be explained as being due to atmospheric electricity.

Some statistics on lightning strokes compiled by the war ministry of Austria-Hungary may at first glance appear rather puzzling, says The Trade Journals Review. They refer exclusively to fortifications and buildings under this department. During 1893 there were 7,979 such buildings, in 3,642 groups. Of these, 1,086 were provided with lightning protectors; the far greater number of 6,893 buildings were without conductors. Forty-two buildings were struck; 29 of those were protected. That is to say, 2·67 per cent. of the protected buildings were struck and only 0·40 per cent. of the unprotected. In 1894 those percentages were 3·25 and 0·087; in 1895, 7·41 and 0·086. The increase in 1895 looks very peculiar; but it turns out that this increase concerns only one district, that of Cattaro, in Dalmatia, where thunderstorms are always frequent, and that on the whole the year 1895 was not exceptional in thunderstorms. Then there is the very marked preference of lightning for protected buildings, which seems to suggest that conductors are worse than useless. The statistics comprise, however, all cases where lightning has taken the path provided for it, and on the whole they prove that the conductors have done their duty. Without going into technical details, the able analysis of the statistics by Dr. Wächter, in the Mittheilungen des Artillerie und Genie Wesens, establishes that, whatever be the theory of lightning conductors, we are not wrong in fitting exposed buildings with conductors joined to the underground water. The old-fashioned plates, buried in holes packed with coke, failed in many instances. The preference of lightning for certain conductors, some of which were struck, several up to 21 times, simply proves that the conductors were placed in suitable places. The present paper does not deal with different types of conductors, these having been discussed by Col. Hess in 1889.

MISCELLANEOUS NOTES.

Trondhjem, the ancient capital of the Norwegian kings, is celebrating the 900th anniversary of its foundation.

The directors of the Furness Railway Company have decided to abolish second class passenger accommodation; but supplementary reserved tickets will be issued to holders of third class tickets at a small extra charge. The carriages will be labeled "Reserved tickets." This is an entirely new departure in the conduct of railway passenger business.

It appears that from the town of Lee, in western Massachusetts, come some of the strongest marbles in the world, as they are found equal to bearing a weight of 13,460 pounds to the cubic inch; but the strongest American limestone comes from Kingston, N. Y., showing a capacity to stand 13,900 pounds pressure to the cubic inch. Tuckahoe marble will bear 12,950 pounds to the cubic inch, this being more than the well known red granite of the Bay of Fundy region, the limit of this latter material being 11,813. The trap rocks of New Jersey and the dolomites of Staten Island are rated the strongest stones in the United States, their crushing resistance being 24,000 pounds to the cubic inch. Rhode Island granite crushes at 17,750 pounds to the cubic inch, that of Virginia will bear 21,500 pounds, and that from the quarries of Maryland 19,750 pounds. New England granites, in general, vary somewhat from these standards.

The Paris correspondent of the British Medical Journal mentions a curious case reported to a Bordeaux society by Dr. Ginestos. The subject was a young man who has, since the age of ten years, had an irresistible impulse to count the letters contained in a word or phrase that he hears, sees, speaks, or thinks. This habit is practiced from the time he wakes to the time he goes to sleep. At night he sleeps without dreaming. When he does not talk, he invents phrases and counts the letters in them. Thirty-two is a number which gives him satisfaction; thirteen displeases him, but nevertheless he does not recoil from arranging phrases with thirteen letters. This unceasing automatic operation does not in any way interfere with his daily work, or reading, or carrying on a conversation. Unless previously informed it would be impossible and extremely difficult for any one to detect the silent mental labor the young man—he is now twenty-seven—is always engaged in.

Colored glasses are generally produced by fusing oxides with the glass; the whole mass is colored. Léon Lémal colors the surface by penetration, and obtains, according to La Nature, colored patterns of striking novelty. A bit of silver salt is placed on the glass, and the glass heated up to 500° or 550° C.; the excess of salt having been removed, the surface will appear of a more or less deep yellow. The depth to which the color penetrates depends upon the time, the shade upon the quantity of salt applied. In five minutes, the top layer of glass, 0·17 millimeter in thickness, was colored; after an hour, that thickness was doubled; in eighteen hours, a plate 1·6 millimeter (1/16 inch) thick was colored throughout. The color appears both in reflected and transparent light, and the yellow is said to be distinguished by a fine greenish or bluish fluorescence. Other metallic salts can be used, gold, copper, iron; silver with a little copper gives a red. The process is exceedingly simple. To transfer a lace pattern upon glass, it suffices to dip the lace into very diluted solution of nitrate of silver and then into potassium sulphide. Photographic collodion negatives can be directly applied to the surface.

In a paper on "The Use of Wind Power in Village Water Supply," in the Journal of the Royal Agricultural Society, of England, Mr. A. L. Y. Morley describes the method which has been successfully pursued in securing an adequate and constant supply of water in two adjoining villages on Lord Spencer's estate in Northamptonshire. The supply of water is obtained from a depth of 200 feet, and is pumped by means of one of Titt's simplex wind engines into a reservoir on the side of the hill, from which at 465 feet above the sea level the water flows to the various points of consumption by natural gravitation. The reservoir is a double one with a capacity of 180,000 gallons. The winter consumption is about 5,000 gallons per day, but in summer when stock are at pasture about 1,000 gallons extra are needed. A population of some 600 people is supplied with water all the year round, and the standards, by Guest and Chrimes, from which the water is drawn, are ingeniously arranged so as to avoid waste through carelessness on the one hand and obstruction from frost on the other. The cost of the reservoir was £530, and of the wind engine £275, the total cost of the entire works, including the considerable lengths of iron piping required, being £2,350. During the four years the works have been in operation there has never been the least anxiety lest the water supply should give out through failure of wind power.

An English journal states that "Australia is going to give us a surprise in the shape of a consignment of two tons of sample tobacco which are now stored at Wangaratta awaiting a touch of humidity in the final stage of treatment before being shipped to England. The Victorian Agricultural Department is sending it on, and it will be packed in the American style, in hogsheads of half a hundredweight each. In quality it is said to be like the tobacco of Kentucky, Missouri and Ohio, and more Western States, rather than like that of Virginia, but it would not necessarily be inferior on that account, especially if the comparison should apply to the Maryland growth, which is the prime favorite in the States. However, there is a wide scale of prices as there is a wide range of qualities. Virginia leaf realizes here all the way from 3d. to 7d. per pound, bright leaf from 4d. to 14½d. per pound, dark Virginia stripped leaf (with the stalks taken out) from 4d. to 10d. per pound, and bright leaf stripped from 4½d. to 15½d. per pound. The Victorian article is a medium colored leaf, the dark and light qualities being intermixed. Heavy dark tobacco, with which the Victorian leaf will probably rank, fetches in the English market 7d. to 8d. per pound for prime, while stripped Western brings 7½d. to 8d., short to middling 5d. to 6d. and the lowest grades from 2½d. to 4d. per pound. If the tobacco from the antipodes turns out satisfactory, the prices realized will no doubt be found equally so."

SELECTED FORMULÆ.

Inking Typewriter Ribbons.—Take vaseline (petrolatum) of high boiling point, melt it on a water bath or slow fire, and incorporate by constant stirring as much lamp or powdered drop black as it will take up without becoming granular. If the vaseline remains in excess, the print is liable to have a greasy outline; if the color is in excess, the print will not be clear. Remove the mixture from the fire, and while it is cooling mix equal parts of petroleum benzine and rectified oil of turpentine, in which dissolve the fatty ink, introduced in small portions, by constant agitation. The volatile solvents should be in such quantity that the fluid ink is of the consistence of fresh oil paint. One secret of success lies in the proper application of the ink to the ribbon. Wind the ribbon on a piece of cardboard, spread on a table several layers of newspaper, then unwind the ribbon in such lengths as may be most convenient, and lay it flat on the paper. Apply the ink, after agitation, by means of a soft brush, and rub it well into the interstices of the ribbon with a tooth brush. Hardly any ink should remain visible on the surface. For colored inks use Prussian blue, red lead, etc., and especially the aniline colors.

Aniline black	½	ounce.
Pure alcohol	15	"
Concentrated glycerine	15	"

Dissolve the aniline black in the alcohol, and add the glycerine. Ink as before. The aniline inks containing glycerine are copying inks.

To Remove Oil and Grease Spots from Colored Leather.—One of the most annoying things in shoemaking is grease spots on colored leather, and the numerous inquiries as to how to remove them show that they occur only too often. We, therefore, believe the trade will learn with interest that, after innumerable experiments, costing much time and money, a means has been found for removing grease spots from leather without changing its color.

Any one who has tried to clean spotted leather by known processes will have become convinced that they are all defective. The use of chalk is complicated, and requires a great deal of time. Spirits of wine injures the color; benzine does the same, with the addition that it attacks at the same time the fatty substances necessary to preserve the fiber of the leather, thus being doubly injurious. Applying hot iron over the grease spot, after covering it with blotting paper, offers no sure result. So other means had to be sought for. Thus it was that finally a solution of gutta percha was tried, with surprising results.

It is true that at first some failures were recorded, but these were due to the employment of benzine as a solvent. There was no doubt that the solution of gutta percha in benzine would remove the grease; but all around the place where the mixture had been applied, a dark circle still remained to show the spot.

Finally, a solution of gutta percha was prepared by pouring carbon bisulphide into a bottle of suitable size, containing the non-vulcanized gum, and allowing it to stand about twenty-four hours. The solution is moderately liquid, and, after shaking it actively several times more, rubber is gradually added, until the solution becomes of gelatinous consistency. This mixture was applied in suitable quantity to colored leather which had been smeared in fish oil, and allowed to dry two or three hours. The subsequent operation consists merely in removing the coat of gum from the surface of the leather—that is, rubbing it with the fingers, and rolling it off the surface.

The color is not injured in the least by the sulphuret of carbon; only those leathers on which a dressing containing starch has been used look a little lighter in color, but the better class of leathers are not so dressed. As to the dried gum, it can be redissolved in sulphuret of carbon and used over again.

The new process consists, then, simply of the application of a very stiff solution of gutta percha in carbon bisulphide, forming a coating of from one-fourth to one-half centimeter thick over the grease spot, leaving it to dry; and afterward removing it. As the gum can be used over and over again, and only the carbon bisulphide has to be supplied, the process is very economical.—From Neue Wiener Schuhmacher-Zeitung.

Blue-Black Ink.—

Aleppo nut galls "blue"	4½	ounces.
Cloves bruised	⅛	"
Cold water	40	"
Ferrous sulphate (purified crystals)	1½	"
Sulphuric acid	35	drops.
Sulphate of indigo	¼	ounce.

Macerate the nut galls and cloves in the water during a fortnight; then press and strain through a cloth filter, add the ferrous sulphate previously powdered, dissolve, and add the acid and indigo solution. Shake or stir the mixture well; then set it aside for a week, and filter it. The nut galls should be free from insect perforations. The sulphate of indigo should be used in the form of a thinnish paste, neutral or nearly so.—Pharmaceutical Era.

A Means of Polishing Machinery.—The chemical laboratory of the industrial museum of Batavia recommends a mixture of—

Oil of turpentine	15	parts.
Oil of stearine	25	"
Jeweler's red	25	"
Animal charcoal, of superior quality	45	"

Alcohol is added to that mixture in such a quantity as to render it almost liquid, then by means of a brush it is put on those parts that are to be polished. When the alcohol has dried, the remaining cover is rubbed with a mixture of 45 parts animal charcoal and 25 parts jeweler's red. The rubbed parts will become quite clean and bright.

Solution for Removing Nitrate of Silver Spots.—

Bichloride of mercury	5·0	grammes.
Ammonium chloride	5·0	"
Distilled water	40·0	"

Apply the mixture to the spots with a cloth, then rub. This removes almost instantaneously even ancient stains on linen, cotton or wool. Skin stains thus treated become whitish yellow and soon disappear.—Mntsch. f. Prakt. Derm.

THE ELECTRIC TRANSPORTATION SYSTEM OF FAIRMOUNT PARK, PHILADELPHIA.

ONE of the most interesting and novel electric lines in this country is that recently installed within the confines of Fairmount Park, Philadelphia. This attractive park is the largest and most important of the public pleasure resorts in Philadelphia, and in fact is the largest public city park in the world and covers 2,740 acres. It is attractively located on both sides of the Schuylkill River, which divides West Philadelphia from the older part of the city, and is quite accessible from the latter, the entrance at Twenty-fifth and Spring Garden Streets being only about a mile in a direct line from the City Hall. The park is noted for natural attractions and artificial improvements, as well as for its extent, in all of which it ranks among the first in the world among similar undertakings.

Although traversed by many fine carriage drives and walks, the very size of the park, which, like the city, was laid out with exceedingly generous proportions, has made many portions of it inaccessible to all except sturdy pedestrians or those who could drive or ride to the points furthest distant from the entrances. In this way many of the most beautiful localities within its borders have been practically unknown to the large mass of citizens; but the proposals which have been made from time to time heretofore to open these portions to visitors by means of a railway have always been defeated, owing to the fear that the construction of a transportation system would destroy or seriously injure the natural attractiveness of the park. The subject was again taken up, however, several years ago, and plans were prepared showing how an electric line making a circuit in the park could be built without a great destruction of the natural scenery, and after much debate among the park commissioners a franchise for such a line was finally granted the Fairmount Park Transportation Company. The result is so at variance with the popular idea that a railroad line, and particularly a trolley road, is necessarily conspicuous and must detract in a park from the natural scenery, that a description of the methods by which the results are reached will be of interest.

On reaching the park the visitor's first surprise is to find the cars standing on the edge of the lawn with almost nothing suggesting a railway in sight. While the usual overhead work is in place, it is not conspicuous, owing to the openness of its surroundings, while on the ground only two rail heads are seen stretching away through the grass. The space between the rails is completely filled in and sown with grass. The element of danger is eliminated by avoiding, from one end of the park to the other, every grade crossing of even a foot path. The line dips sharply under many of the carriage ways; it winds along valleys, clings to the hillsides, follows up and down ravines, and is as utterly unobtrusive as two lines of iron could be on the landscape. Conforming so closely to the contour of the land, there are few embankments or cuttings that are even noticeable features in the landscape until one is close upon them. Even the power station and car house are hidden from sight, as will be described later.

The line has a length of 8¼ miles, along which stations are constructed at distances of about three-quarters of a mile apart, and at these stations only are passengers allowed to enter or leave the cars. The road being in the form of a loop, the cars run in one direction only. For short distances at the southern and eastern ends the tracks lie parallel, but for the remainder of the distance they are widely separated. The whole line is inclosed by a wire fence of twisted steel. The track is laid with 90 lb. T rail laid on yellow pine ties 6 in. × 8 in. × 8 ft. in size and spaced 2 ft. centers. The rails are bonded with the Brown plastic bond. All switches are of standard steam railroad pattern. As all banks and cuts are sodded with grass, they are of a different slope than is usual. Those on banks and cuts less than 10 ft. deep are proportioned as one to three, and on cuts or banks more than 10 ft. in depth the proportion is one to two.

In preventing grade crossings over drives and pathways, the company has constructed a number of viaducts, stone arches and iron bridges, the total number of which is twenty, including a bridge over the Schuylkill River, which is 227 ft. long. This bridge has a double track for the railway, a 40 ft. wide carriage drive and a 12 ft. wide sidewalk. The height from the drive to low water is 80 ft. This bridge has four river arched spans each 208 ft. long.

The rolling stock consists of sixty cars, ten of which are closed motor cars. Of the fifty open cars, twenty are fitted with motors and the remainder are trailers. All the cars are of unusual width, being 7 ft. 10 in. in the clear at the seats. The gage is 5 ft. 2½ in. The closed cars have 32 ft. bodies and are 42 ft. over all. They are 8 ft. 9¼ in. wide at the posts. These cars seat forty-eight passengers in cross seats, which are 35 in. long and have a 21 in. aisle between them.

The open cars were also specially designed for the service and differ essentially from other cars of a similar type. In length they measure 47 ft. over the crown pieces or 38 ft. at the corner posts. The width over the posts is 8 ft. 10 in. This gives a long seat which accommodates six persons comfortably. As the seats are spaced 3 ft. in the clear, ample room is given those entering or leaving a seat. The spaces are the same as those in the Broadway cars in New York City, and in the case of a crowd there is ample standing room for a row of people in front of those who are sitting. There are eight reversible seats and four with stationary backs, giving a seating capacity of seventy-two.

The cars are mounted upon 27-B trucks, a modified form of the "Perfect truck" of the same firm. These trucks are equalized, and have a swing motion which is cushioned by means of springs within the swinging links. This feature makes them very easy and steady on curves even when going at a high rate of speed. A long elliptic spring on each side is so arranged as to take the place of the equalizer.

They give a short wheel base, bring the body of the car low and do not kick up under the action of brakes. This road tests the riding qualities of the cars most severely, as it is full of curves, many of them of quite short radius. Under these conditions the trucks are riding with remarkable ease and smoothness.

The electrical equipment consists of four motors to a car and electric brakes acting on all axles, on the trailer cars as well as the motor cars. The cars are equipped with G. E. 1,000 motors and controllers, specially manufactured for the Fairmount Park Transportation Company, controlling both motors and brakes. The operation of the road is protected with the Hall block signal system.

The overhead construction work of this line is one of the most substantial in the country and is of a peculiar nature, owing to the heavy traffic and the location of the road through a series of rock and clay cuts, over high earth embankments and through and over stone and iron viaducts.

Over 60 per cent. of the poles are set in solid rock and about 15 per cent. are of special lengths and construction, varying all the way from a 28 ft. pole, weighing 750 lb., to a pole 65 ft. long, weighing 2,800 lb. There are three standard weights of poles on the line—on straight track a 7 in. by 6 in. by 5 in. 28 ft. pole, weighing 750 lb.; for pull-offs and special strains a 1,000 lb. pole of same dimensions, and for special strains, at the end of the line, an 8 in. by 7 in. by 6 in. 28 ft. pole, weighing 1,800 lb. The poles are set in concrete 6 ft. deep, in 2 ft. diameter holes. On straight track, poles are spaced 100 ft. apart and on curves 50 ft. apart.

The span wires are $\frac{7}{16}$ in. diameter steel cable, insulated from poles by special heavy Macallan turnbuckles. The trolley wire is attached to the span wire through a special cap and cone insulator. The trolley wire is a No. 0000, and it is held in the insulators by soldered ears weighing a little over double the standard weight ear used on No. 00 construction work. The wire is spliced with heavy copper sleeves. All feeder taps are provided with 600 ampere single switches, heavy line breaks and General Electric Company's lightning arresters. On double track the trolley wires are cross connected every 1,000 ft. Under bridges, of which there are a large number, the trolley wire is secured in heavy yellow pine troughs with standard cap and cone barn hangers. All curve work is of exceptionally heavy construction, owing to the use of heavy No. 0000 trolley wire and the constant traffic.

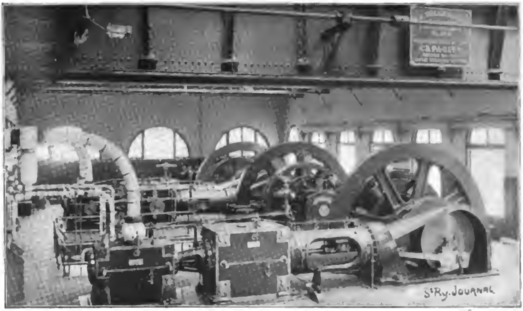
The feeders are underground and are laid in 2¼ in. Williamsport creosoted wooden ducts. Roebling paper covered feeders are used. This feeder system runs across a number of valleys containing streams of water and many of the manholes are 20 ft. deep. The contractors for the overhead and underground systems were Pepper & Register. Mayer & Englund supplied the overhead appliances.

A short distance below the car house is situated the engine and boiler house. This building was designed by Axel H. Engstrom and Edw. B. Ives, and is also much below the surrounding level. The stack is only as high as the roof of the house itself, and from a little distance the building is entirely hidden from sight by the tree-covered banks.

The engine room is 156 ft. by 55 ft. in size, and the boiler room of the same length and 36 ft. wide. A spur from the adjacent railroad is carried close to the south wall of the boiler room and passes over coal vaults, the coal being dumped into the vaults by means of chutes. The station has sufficient storage capacity for one month's supply of coal.

At present there are installed three tandem compound condensing Corliss engines, furnished by Robert Wetherill & Company. There is room in the station for two more engines. The engine foundations are of brick and of unusually large proportions. Each foundation rests upon a concrete bed. This bed of concrete is 24 in. in thickness. The engines have cylinders 20 in. and 36 in. by 48 in. in size, and each makes 90 revolutions per minute.

The flywheel is 20 ft. in diameter and weighs 40 tons. It is made in sections, an arm being cast with each rim section. The rim segments are tied together by heavy wrought iron links. Each engine is directly connected to a 300 kilowatt generator, furnished by the General Electric Company.



ENGINES AND GENERATORS—FAIRMOUNT PARK POWER STATION.

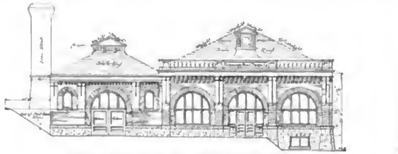
The boiler room at the present time contains six Berry boilers, built by Wetherill & Company, and space has been provided for the installation of two more. Each boiler is of the vertical type, occupies a floor space of 11 ft. by 11 ft. in size, and is rated at 250 horse power. The gases from the boilers pass to an overhead smoke flue leading to two sets of economizers, from which the waste gases are exhausted by a pair of exhaust fans discharging into a short steel stack 7 ft. in diameter. The economizers are so connected to the flues that one set receives the waste gases from the boilers at one end of the boiler room, while the other receives the waste gases from the other boilers. All of the waste gases, however, may be passed through either economizer. A single fan, 10 ft. in diameter and 4 ft. wide, driven by a direct connected engine, exhausts each economizer, and both fans discharge into a common stack. The fans and economizers were furnished by the American Economizer Company. The economizers have 256 pipes each. The sections are eight pipes wide and each pipe is 4½ in. in diameter and 9 ft. 4 in. long. Each economizer has a heating surface of 2,944 ft.

The exhaust steam from the engines passes into a 20 in. exhaust main located under the floor of the engine room. This main is divided into two sections by a 20 in. valve and each section has a pipe leading to a twin vertical air pump made by the George F. Blake Manufacturing Company, connected to a jet condenser. A branch from the exhaust pipe to the condenser 16 in. in size, and fitted with a relief valve, unites with the free exhaust from the other half of the system to form a 20 in. pipe leading to the atmosphere.

The steam cylinders of the air pump are 12 in. in diameter, and the bucket of the air pump, which is single acting, is 25 in. in diameter. Each has a stroke of 18 in. The injection water is taken from the adjacent Schuylkill River through a 16 in. pipe. These mains pass to the condensers in a trench between the two concrete beds underneath the engine foundation;

The discharge from both condensers is 16 in. in size, and leads back to the river.

All of the auxiliaries of the plant, such as the air pumps from the condensers, drip and feed pumps, fans, engines, etc., are supplied by branches from an auxiliary steam main supported from the wall of the engine room. The exhaust steam from all of these auxiliaries is collected into a 6 in. pipe and passed through a Berryman feedwater heater with 1,000 sq. ft. of heating surface from which the surplus exhaust steam passes into the free exhaust pipe from the main engines. The heater, however, may be by-passed if desired. The boiler feedwater may be taken either from the river or from the discharge from the condensers. The water, which is taken from the discharge from the condensers,



SOUTH ELEVATION OF POWER STATION.

is passed through a filter made to remove the oil in order that it may not enter the boilers.

The boiler feed pumps are two in number and the water is forced by them through the feedwater heater, where it is raised to about 200° temperature, and from the heater either directly to the boilers or through the fuel economizers as desired. The fuel economizer may also be by passed if desired.

The cost up to date for the 8¼ miles of line is estimated at $2,000,000, including $500,000 paid for the franchise. To earn returns on this investment a large traffic is, of course, necessary, as the fares are limited to five cents per passenger, independent of the length of ride. The traffic so far has been enormous, and points to a most successful financial return upon the investment. Thirty-five hundred passengers have been carried in one day, the maximum load to the station on this day being 3,400 amperes, while the running expenses were $300.

We are indebted to The Street Railway Journal for cuts and particulars.

THE ECONOMY AND UTILITY OF ELECTRICAL COOKING APPARATUS.*

By JOHN PRICE JACKSON.

THE tests of electrical cooking apparatus detailed in this paper were made with the hope of obtaining a method of cooking that would be satisfactory with a minimum risk of fire. During the past winter a serious fire, which might readily have become disastrous, occurred in one of the buildings of the college with which the writer is connected, caused by the use of an alcohol stove. As this institution is lighted and furnished with power by electricity, it was naturally felt that such a danger should be avoided, if possible, by the use of electrical appliances. It was also desired to ascertain whether at least a portion of the cooking in the woman's department of the college could not be done satisfactorily by electricity.

To determine these points, I procured from the American Electrical Heating Corporation, of Boston, through the courtesy of Mr. J. E. Sayles, the following pieces of apparatus:

One oven, 18" × 9" × 18", having three heats, 3, 10 and 17 amperes respectively.

Three stoves of 2, 4 and 5 amperes respectively.

Two flatirons of 1·5 and 6 amperes capacity.

One broiler of 12 amperes capacity.

One curling iron of ½ ampere capacity.

The pressure used by these is 110 volts.

The stoves are round disks of iron, on the under side of which the heating wires are embedded in a non-conducting, incombustible compound. The oven is a box, so thoroughly heat insulated that the outside metal covering never reaches a temperature uncomfortable to the hand. The broiler is made of a corrugated metal surface, slightly tipped from the horizontal, with a drip groove at the lower edge for catching the meat juices. The flatirons are similar in construction to the stoves, the larger one having a low current switch, which enables the operator to control the heat.

In all these appliances the heating coils are so arranged that the energy is largely concentrated at useful points. They are also supplied with supports and bases which will not conduct heat.

The efficiencies of the two larger stoves were obtained by heating two pounds of water to the boiling point and measuring the power supplied by a calibrated wattmeter. The cooking vessels used were ordinary stewing pans, with the bases nearly of the same size as the tops of the stoves. The efficiencies, considering the ratio between the amount of heat absorbed by the water and the amount received by the stoves, were:

For the larger or No. 1, 48·9 per cent.

For the next size, " 2, 43·1 "

These efficiencies could be increased by having the pans made to fit the stoves exactly, and still further by carefully covering the pans, lids and exposed portions of the stoves with a non conductor of heat.

When it is desired to boil water, the best plan is to place an immersion coil in a properly heat-insulated pot; such an arrangement should give an efficiency of from 90 to 100 per cent. We unluckily did not have such a coil at our disposal.

It was impossible to measure the cooking efficiency of the oven, but as it was merely warm on the outside after potatoes or bread had been baked and "done to a turn," the efficiency is high. In baking, the current was turned on and the oven allowed to heat for five minutes before the articles to be cooked were placed within, and the current was turned off from ten to twenty minutes before the baking was done, when the heat of the oven was sufficient to complete the operation. The broiler was manipulated in much the same manner, thus utilizing the greatest possible amount of heat. This electrical apparatus was used for several weeks in cooking most of the meals for a family of six.

The following table indicates the amount of cooking done for the first breakfast, dinner and supper respectively, and may be taken as a fair average of the whole period.

All costs have been estimated on the basis of 10 cents per kilowatt hour, the average rate charged for residence electrical supply in a near-by town. The foods were not measured, as it was believed more desirable to determine whether in a long period of cooking the apparatus would prove satisfactory for a family of given size.

The largest stove is designated No. 1; the next size, No. 2; the third size, No. 3; the broiler, B, and the oven, O.

5.44	1, off		

Kilowatt hours, 8·39 Cost, 8·39 cents.

Four pies can be baked in the oven at an expenditure of 0·62 kilowatt hour and a cost 6·2 cents or 2·05 cents per pie. Two large loaves of bread were baked with the current on the oven 50 minutes, at an expenditure of 1·22 kilowatt hours, a cost of 12·2 cents or 6·1 cents per loaf. Four rather small-sized loaves could have been baked as readily. Biscuits with about the same expenditure of energy as in the case of pies. The broiler utilized about the same amount of energy for all kinds of meat as indicated in the table. The cost of soup sufficient for the family was about 4·5 cents.

The result of the whole series of meals was a cost for electricity of 13·1 cents per meal. The heating of water for washing the dishes took an additional 0·35 of a kilowatt hour per meal, which raises the cost to 16·6 cents per meal.

To determine the relative cost of cooking with electricity and coal, the same foods were cooked on the No. 8 Othello coal stove ordinarily used by the family. The coal was carefully weighed. The results gave an average of 12·6 pounds per meal, which at $5 per ton gives a cost of 3·15 cents per meal.

The results show the cost of cooking by coal to be about 19 per cent. of the cost of cooking by electricity.

Ironing was done for the same household a number of times. The heavy articles were done with the large iron; while for fancy dresses and light articles the small iron was used. The average time taken was four hours, and the expenditure of energy in kilowatt hours was 2·27. This made the cost of the ironing 22·7 cents.

An equal number of tests was made using the coal range, the fuel being carefully weighed. For the same sized wash, the ironing took five hours, at a cost of 12·25 cents. This shows the cost of energy by the use of coal to be 54 per cent. of that by electricity.

The results of the cooking tests seem to indicate that for the usual cooking of a family for the whole year the expense would be larger than would be ordinarily acceptable, notwithstanding the great advantages in other respects. However, in the following classes the utility of electrical cooking utensils should be great:

1. For light housekeeping, such as is practiced in small city apartments, and in many larger houses during the summer months, no other method presents so many desirable features. The dirt of coal and ashes, disagreeable gases and abnormal temperature due to a coal stove are entirely avoided. For such housekeeping a disk stove using 500 or 600 watts and a broiler using about 1,200 watts would be sufficient for a small family and would cost from $20 to $30. A teakettle or immersion coil might be added at a cost of from $6 to $10. A special pair of wires would of necessity have to be run into the cooking room from the house or apartment supply mains. The latter would ordinarily warrant the extra call that would be made on them in this way. For similar purposes coal oil, gas or gasoline are frequently used, but with the inherent disadvantages of greater heat in the room, offensive odors, comparative uncleanliness and danger.

2. This form of cooking apparatus could be used with facility in boarding houses and restaurants for purposes that require an even temperature, such as is needed in baking griddle cakes, boiling eggs, etc.

3. Where electricity is available, nothing could be more convenient than a small electrical stove, requiring 300 or 400 watts, for the many uses to which at present the alcohol flame is put, such as the afternoon tea.

TYPICAL PASSENGER STATION—FAIRMOUNT PARK.

ENTRANCE TO ONE OF THE ARCHES.

* A paper presented at the fourteenth general meeting of the American Institute of Electrical Engineers, Eliot, Me., July 28, 1897.

kettle, chafing dish, toaster, etc. This use of alcohol is most unsafe as regards danger from fire, and could well be discarded for electricity, which is absolutely safe when properly installed, as well as being more convenient and better in other respects.

4. In the shop, the glue pot, solder pot, brazing iron, etc., can be heated advantageously by electricity, and one of the most gratifying consequences of our experiments has been the decision to put such an equipment in our college shops.

5. The test of the electrical flatirons showed them to be more economical than the old form, when the saving of labor is taken into account. Not only is there a saving in time, but the severity of labor is much lessened. Our experience is that a laundress who has used an electrical iron would be exceedingly unwilling to go back to the old form.

A small flatiron of two or three amperes attached to the ordinary lighting fixture in a dressing room is a great convenience; and with the electric teakettle and curling iron is destined to become essential in the modern home.

Concerning the question whether the use of electricity had proved satisfactory in its operations in the cooking tests described, the housekeeper in charge said: "The instruments were excellent in every respect. We were able to cook more rapidly, to keep the heat at just the right point, and could readily prevent over-cooking or under-cooking. While we were using electricity every dish was perfect. When I think of these advantages and of the cleanliness and convenience of the utensils, I sincerely hope that some of them at least may be retained in the house permanently."

The general results of the tests were of such a nature that the writer is warranted in the belief that if central station managers would more generally introduce exhibition equipments of these domestic utensils, a new call on their station capacity would develop, of which the larger proportion would be during the light load periods.

I wish to acknowledge my indebtedness to Mr. Rudolph F. Kelker, of Harrisburg, Pa., for his valuable aid in carrying out the work briefly described above.

THE BEHAVIOR OF ARGON IN X RAY TUBES.*

IN continuation of some experiments made by Prof. Callendar in the early part of 1896, the authors have studied the behavior of argon in X ray tubes of various types. The phenomena presented by a tube filled with carefully dried and purified argon are in many respects peculiar, as compared with those presented by other gases under similar conditions.

In the early experiments above mentioned it had been our custom to keep the X ray tube connected with the pump, which was used as a reservoir of dry air during long exposures. The gas, which was absorbed by the working of the tube at a high vacuum and a long equivalent spark gap, was restored from time to time, as the vacuum became too high, by letting a little air in from the pump by means of a convenient tap. In this manner it was possible to operate the tube at a very high rate of efficiency for two hours or more at a time. These long exposures were required for some experiments on the velocity of the X rays, which have been described in a communication to the Canadian Royal Society, May, 1896.

It was noticed on several occasions, after one of these long exposures, that there was considerable blackening and sputtering of the electrodes, and also that the pressure of the air in the tube had increased considerably above the degree of vacuum required for the production of X rays when the tube was first exhausted. After allowing the tube to rest for a few hours, although there was very little increase in the pressure, it was also observed that no cathode rays were produced until the discharge had been passed for some time. It appeared probable that some of these effects, which are recorded in the paper above mentioned, were due to the accumulation of argon in the tube. The spectral lines of that gas were on some occasions faintly discernible in parts of the tube, but no systematic spectroscopic observations were taken.

In making further investigations on the behavior of argon, we hoped to find that, owing to its natural inertness, the vacuum would be of a very permanent type as compared with other gases. We also hoped that its monatomic character would afford features of interest.

For the preparation and purification of the argon used in these experiments, the Cavendish spark method was adopted, as described by Rayleigh and Ramsay. For this purpose a special transformer was constructed, the primary and secondary of which were wound on different parts of the core. The primary was connected to the 100 volt lighting circuit. The secondary gave 10,000 volts on open circuit, available for starting the arc, but the voltage on the arc when running was only 2,000. The secondary could be short circuited, owing to the arrangement of the winding, without materially increasing the current or running any risk of burning up the coil. The apparatus could thus be left running safely by itself day and night without wasting any power on resistances. After concentrating the argon to about 60 or 70 per cent. in the flask it was further purified in a test tube apparatus, constructed so as to contain the minimum of liquid. The excess of oxygen was sparked off with hydrogen and the residue removed by absorption with alkaline pyrogallate. The argon thus purified was kept in a bulb containing P_2O_5.

In the first set of trials of this argon in X ray tubes, a Fleuss mechanical pump was used, which permitted very rapid exhaustion of the tubes, but had no arrangement for measuring the high vacua. The vacuum was estimated in these cases by the appearance of the tube and the width of the dark space.

The first tube tried had two aluminum electrodes, and had been lying open to the air for some time previously. It was exhausted and washed out two or three times with dry argon, and then sealed off at a good X ray vacuum. Each operation occupied only two or three minutes, and the vacuum has since that date deteriorated slightly, probably owing to insufficient removal of residual gas from the electrodes, but it still gives sufficient light to see the bones of the hand. The tube during exhaustion presented exactly the same appearances, except in color and spectrum, as if it had been filled with air.

The second tube had been worked up to a sparkless vacuum some weeks previously and had been frequently renovated by heating. It had an aluminum cathode and a platinum anode. It was connected to the pump and exhausted as soon as possible after opening. It was then filled with dry argon up to a pressure of one-fifth millimeter and exhausted to an X ray vacuum five times in succession. The glow on the cathode inside the dark space showed the F line of hydrogen and also the C line more faintly. These lines probably indicated the elimination of hydrogen from the electrodes, especially the cathode, as they became fainter with each repetition of the process of washing out.

At the sixth filling of the tube the pump was worked for ten strokes only. The cathode then began to sputter and blacken the tube and the argon was apparently absorbed, as the discharge refused to pass in three minutes. Fresh argon was again admitted, the coil was left running, but the pump was not worked at all. The spectroscope this time showed only blue argon without any trace of hydrogen. The concave aluminum cathode sputtered violently and partly melted down. In less than two minutes the discharge refused to pass through the tube, which was then sealed off.

The coil used in these experiments was a very small one, which gave a two inch spark with difficulty when running on a large eight volt battery.

The next tube upon which we experimented was a double focus tube, containing two aluminum cathodes and a platinum anticathode. This was washed out with argon and exhausted eight times with the two inch spark coil running all the time. The direction of the discharge was frequently reversed, but no trace of absorption could be observed. The argon lines always disappeared and the hydrogen lines, especially F, became faintly visible inside the cathode as the tube approached an X ray vacuum. The tube at each exhaustion gave fairly bright X rays and showed no blackening or sputtering. The hydrogen lines showed more brightly close to the cathode than in the body of the tube, where the argon lines were most conspicuous. The hydrogen appeared, in fact, to be coming out of the metal. The glass walls of the tube were in a very dry state, as it had been previously heated and exhausted.

Finding that we could not get rid of the residual hydrogen with the coil, we had resort to the alternating current, which we had previously found very effective in tubes with double electrodes. It appears that the elimination of hydrogen takes place chiefly, if not entirely, at the cathode. With the first application of the alternating current, the hydrogen lines showed extremely bright. The tube was then exhausted. In fifty strokes the discharge refused to pass. On refilling with argon to a pressure of one-tenth of a millimeter, the blue glow inside the dark space showed only argon and no hydrogen. The pump on this occasion was not worked at all, but the gas apparently was absorbed, and the discharge refused to pass in about three minutes. There was some sputtering of the electrodes and blackening of the tube, but the aluminum, though blistered, was not melted. The experiment was repeated twice with the same results. On reconnecting the tube to the two inch spark coil, the same absorption was observable, but less rapid. The electrodes were larger and were less heated than in the case of the first tube.

We concluded from these and similar observations, of which the above may be taken as a sample: (1) That the hydrogen occluded in the cathode played the part of carrier of the discharge from the metal to the gas. (2) That if there were sufficient occluded hydrogen, there would be little or no sputtering of the aluminum. (3) That when no hydrogen was present, the discharge was conveyed from the cathode by particles of the metal itself, which were capable of exciting fluorescence of the glass and of generating X rays wherever they impinged, behaving in fact as cathode rays. (4) That in X ray tubes, as usually exhausted, without excessive precautions for the drying of the gases and the complete removal of residual hydrogen from the electrodes, the residual gas was in most cases hydrogen or water vapor.

In order to test the behavior of other gases as compared with argon, similar experiments in the same tubes were made with dry air, hydrogen, and with water vapor.

With dry oxygen and nitrogen, the absorption of the gas was very rapid at a pressure of one-tenth of a millimeter, if the electrodes were sufficiently heated. Although hydrogen was not observable and was presumably absent, blackening of the tubes was very slight, and a much greater power could be applied than in the case of argon, without melting the electrodes.

With water vapor under the same conditions an X ray vacuum could not be obtained (owing probably to the slowness of diffusion), unless the tube were considerably heated, either with a flame or by means of an excessive current. On allowing the tubes to cool under these circumstances, the vacuum improved very greatly, owing to the absorption by the surface of the glass, and the discharge often refused to pass. Under steady conditions of running at a low temperature, there was no clear evidence of absorption of the water vapor, in spite of the drying tube on the pump.

With carefully dried hydrogen, under the same conditions, the process of exhausting the tubes with the mechanical pump was extremely rapid as compared with the other gases, owing to the greater velocity of diffusion of the lighter gas. With the smaller tubes, ten or twenty strokes were sufficient to give brilliant X rays, starting in each case with a pressure of half a millimeter to a millimeter. There was no marked absorption at any stage of the vacuum, and no trace of sputtering of the electrodes. We expected to find some evidence of absorption by the electrodes or the platinum anticathode, but it is possible that these became saturated with gas very rapidly at an early stage, and ceased to absorb gas at an X ray vacuum. We concluded that hydrogen was the most suitable gas to use in X ray tubes, but it is possible that helium, being also a very light gas, might be equally good if its inert or monatomic character does not lead to the disintegration of the electrodes in the same manner as in the case of argon.

If the great resistance to the passage of the discharge from the cathode to the gas in the case of argon is dependent upon the monatomic nature of the gas, it might be expected that similar phenomena would be observed in the case of mercury. Some mercury vacuum tubes were therefore made in the form of inverted U tubes. The electrodes were liquid surfaces of mercury in each limb, to which connection was made by short pieces of platinum wire, which did not project above the surface of the mercury. These tubes were exhausted and boiled with an alternating discharge passing, until more than half the mercury had distilled over. They then presumably contained only mercury vapor. When cool, the two-inch spark discharge refused to pass at first, but if the tube were tilted for a moment, so as to expose the platinum wire, it appeared that sufficient gas was liberated to enable the discharge to pass without any difficulty. The tubes showed only the mercury spectrum. In the high resistance state, immediately after boiling, the cathode limb, with a larger spark coil, showed brilliant fluorescence and feeble X rays. We concluded from these experiments that a very small trace of another gas was sufficient enormously to reduce the resistance of a mercury vapor tube, and that if the vapor could be obtained quite pure, it would possibly not conduct at all.

To verify more accurately the conditions of vacuum at which these phenomena occurred, the whole apparatus was subsequently connected to an automatic Sprengel mercury pump to which a McLeod gage was attached. The pump and all its connections were carefully tested for leakage, and the drying tube was filled with fresh P_2O_5. We had found in previous experiments of a similar character, made two or three years previously, that sulphuric acid, however carefully prepared, gave off appreciable quantities of water vapor, which would have been quite sufficient to vitiate these results.

Using a large coil and a slow mercury break, to avoid overheating the tubes, we found that fairly efficient X rays were obtained in most of the tubes at an average vacuum of 0·006 millimeter, if the tubes were exhausted in the ordinary way without taking special pains to remove the hydrogen. The H lines always showed faintly in the cathode light before this vacuum was reached. After using an alternating discharge to heat the electrodes, and carefully washing out the hydrogen as far as possible with argon, we found that the pressure corresponding to an X ray vacuum gradually increased up to 0·030 millimeter. Before letting the argon into the tube it was allowed to remain ten or fifteen minutes in contact with the fresh P_2O_5. On omitting this precaution and admitting the argon direct from a bulb containing an old sample of P_2O_5, which was beginning to deliquesce on the surface, it was necessary to raise the vacuum to 0·015 millimeter before X rays were produced. On the other hand, the sudden addition of dry argon at this stage up to a pressure of 0·020 produced no change in the appearance of the tube. It is probable that we never succeeded entirely in eliminating the residual hydrogen, but we concluded from these and similar experiments that the presence of the argon by itself had little, if any, effect on the production of X rays, since the amount present in the tube could be varied within wide limits.

We next endeavored to ascertain at what degree of vacuum the apparent absorption of the argon previously observed could be produced. For this purpose we used two tubes of the double-focus pattern, and an alternating discharge. Taking the first tube slightly damp from the blowpipe, we exhausted it to one-fifth millimeter vacuum with the mechanical pump. The discharge was then turned on and adjusted to heat the tube and electrodes as much as possible with safety, and the pump was not further worked. Under these conditions the remaining water vapor was rapidly expelled and absorbed by the P_2O_5, the tube soon showed a brilliant hydrogen spectrum followed by green fluorescence, the anticathode became red hot, then cooled, and in fifteen minutes the discharge (20,000 volts) refused to pass. The tube was not appreciably blackened. On connecting to the direct current discharge, it gave brilliant X rays. This case is interesting as showing that a very good vacuum may be obtained in these cases by simple absorption.

Dry argon was then admitted into the tube up to a pressure of 0·100 millimeter. At this pressure, in tubes three inches in diameter, with the direct or alternating current, the tube was filled with blue light, and gave a spectrum which was verified to be that of blue argon, without any visible trace of hydrogen or nitrogen. After running the direct and alternating current through the tube for half an hour, the tube became very black, but there was no change in the pressure as measured by the gage. It should be remarked that in measuring these high vacua, the pump was usually stopped to allow time for the equalization of the pressure throughout the apparatus. The alternating current in the primary of the coil was only 2·5 amperes with argon, whereas 4 amperes had been used with air. The latter current, if used with argon, would have melted up the cathodes. Finding no absorption at this pressure, the pump was started to run very slowly, and the same alternating discharge was continued. The sputtering of the electrodes rapidly increased, and at a vacuum of about one-tenth of a millimeter the upper electrode suddenly melted off. Another tube was then tried but met with a similar fate at the same degree of vacuum. The failure was so sudden that it was difficult to control the current in time. If the argon is actually absorbed, it is clear that the phenomenon depends upon very special conditions of temperature and discharge. It is possible that the absorption is only apparent, and corresponds to a very sudden increase of resistance to the discharge at a particular degree of vacuum, such as occurs in an ordinary X ray tube when the boundary of the dark space reaches the anticathode. With greater care, it may be possible to decide this point, but an unfortunate accident to our water mains prevented further investigations at the time. It is clear, however, that the behavior of argon is peculiar, and it seems probable that most of the ordinary cathode ray phenomena are due to residual hydrogen.—Nature.

CHEMICAL PROCESSES IN A GAS PLANT.*

IT is a remarkable fact from the standpoint of the chemist that chemistry occupied itself for many years but little with this important branch of the chemical industry, and even to-day only the largest gas plants in Germany employ a chemist. Yet the gas plant offers to the chemist a wide field of activity, beginning with the purchase of coal and reaching to the selection of burners for the street lamps. The manufacture of illuminating gas, as is well known, has not become any simpler during the last two decades. The purifying methods, it is true, have remained the same in principle, but the apparatus has grown more complicated. This is due to the desire to obtain the greatest results on small areas. In the selection of the apparatus of a new gas plant, the voice of the chemist should be heard, for he understands to judge its effect, while the engineer should naturally occupy himself with the mechanical side of it only. Thus it may happen that the engineer thinks an apparatus good, while the chemist declares it bad.

The work of the chemist in a gas plant may be divided into two parts, namely, in the control of the finished gas, and laboratory work for the purpose of the most profitable production and utilization of the principal product as well as the by-products. As regards the control of the gas, this extends, in the first place, to its illuminating power. In Hamburg a 17 candle gas has to be furnished, which is measured in an Argand burner with a Bunsen photometer. This is done in four photometer rooms at the gas works and two in the city, in order to supply the consumers with as uniform a gas as possible, for it is known that from good coal good and also bad gas can be produced, depending upon the temperature of the retort ovens. In small plants, with a few ovens, this is quickly noticed; but in large plants it is less noticeable, as with many ovens there are always a few which do not come up fully to requirements. In the Hamburg gas works small retorts are in use, the charges ranging from 300 to 500 pounds. All attempts to produce good illuminating gas in large chambers or ovens after the pattern of those used in the coke industry have failed.

The second point to be watched by the chemist is the sulphur contents of the gas furnished. It is known that the gas must be freed from the last trace of sulphureted hydrogen. Sulphur contents in another form, however, are unavoidable, namely, sulphocarbon and sulphurous organic substances. By their combustion in the flame sulphurous acid and, according to conditions, some sulphuric acid are produced. Formerly there was much complaint in Hamburg over the action of the products of combustion of the gas, which attacked metals, textiles, etc. This proved to be simply due to the use of highly sulphurous English coals without lime purification as practiced in England. Lately, since a chemist is employed, it is possible to reduce by the proper selection of coals the high sulphur contents considerably, and the London limit of 22 grains of sulphur to 100 cubic feet of gas is maintained. Concerning the formation of sulphocarbon, this, of course, takes place in the retort already. The sulphureted hydrogen escapes together with the raw gas from the incandescent coal, and forms sulphocarbon with the latter. Highly sulphurous coal yields much sulphureted hydrogen, and for this reason much sulphocarbon, yet compared with the sulphureted hydrogen the quantity of sulphocarbon formed is always very small. Of less importance than that of sulphur is the other customary determination of carbonic acid and ammonium. The former is a remnant from the old lime purification, while now gas is purified by means of iron oxide, and the carbonic acid is left in the gas. Rather high contents of it can hardly be avoided. The London standard for ammonia is 4 grains to 100 cubic feet, but in gas produced by good apparatus seldom more than a trace can be found. Only in works where the apparatus is overburdened it is possible to bring more ammonium into the gas. It is well to determine the heating power of the gas by the Junker calorimeter in order to render it in this respect as uniform as possible. The most careful gas inspection is without doubt practiced in London, where the gas is examined photometrically three times a day at 14 stations, by 23 chemists, who have to analyze it also on sulphur and ammonium.

DETERMINATION OF SULPHUR IN COAL.†

IN the method proposed by Fischer, 1 gramme of coal is placed in a combustion tube containing asbestos or pumice, and is consumed in a current of oxygen. The products of combustion are passed through a washing apparatus containing bromine dissolved in hydrochloric acid, whereby the sulphur dioxide is oxidized and can be estimated as sulphuric acid by precipitation with barium chloride and weighing. To shorten the operation, Fischer also proposed to oxidize the sulphur dioxide by means of hydrogen peroxide and then determine the resulting sulphuric acid volumetrically, by titration with an alkali. This method is considered by the author as lacking precision, five tests performed by him on one and the same coal having yielded appreciably different results. He therefore proposes to modify the method by dispensing with the asbestos (or pumice), which retains a notable quantity of the sulphuric acid—probably in the condition of sulphates—and is very difficult to wash. He also suppresses the hydrogen peroxide, since this substance can rarely be obtained in a pure state, and moreover, by reason of its rapid decomposition, is liable to leave small amounts of sulphur dioxide unoxidized. The coal to be tested is inserted in a combustion tube, the posterior extremity of which is provided with a platinum spiral, and the oxygen is introduced through two pipes, debouching one in front and the other in rear of the capsule containing the coal. The products of combustion are led into a washing apparatus containing a titrated solution of caustic alkali, with a little methyl orange to act as indicator. This solution arrests the carbon dioxide, the sulphur dioxide and the sulphuric acid. When the combustion is terminated the washings of the combustion tube and platinum spiral are united with the alkali solution, and a freshly prepared solution of sodium peroxide, carefully titrated by the aid of methyl orange, is added. The whole is then boiled, and when the whole of the hydrogen peroxide has been decomposed, the total residual alkalinity is determined by means of normal acid. This gives all the data necessary for the calculation of the sulphuric acid fixed, and consequently of the sulphur present in the coal. The results obtained are very accurate, a Donetz coal found by gravimetric analysis to contain 3·65 per cent. of sulphur, yielding by the above volumetric method 3·61, 3·72 and 3·67 per cent. in three separate tests.

MERCURY PUMPS.

MERCURY pumps are, as well known, of great utility in laboratories, but certain difficulties are often experienced in making them work well. It is, therefore, not superfluous to make known the latest improvements that have been introduced into these apparatus.

M. Henriet, in recently presenting a new mercury pump to the French Academy of Sciences, recalled some of the inconveniences of the ordinary apparatus, such as leakages due to the cocks, and which the most careful lubrication fails to prevent, loss of time due to maneuvering of the cocks, and chances of breakages in consequence of ram strokes. The new pump does away with all such inconveniences, columns of mercury being substituted for cocks in its construction. No. 1 of Fig. 1 gives a general view of the apparatus, and Nos. 2 and 3 show the details.

To the lower part of the bulb, B, there is soldered a vertical tube, E, which descends and terminates at f. From the upper part of this same bulb there starts a capillary tube, G, which, curving around it, enters a mercury reservoir, M, situated beneath.

When the mercury descends from B, the air, coming from the orifice, f, enters it and produces a bubbling of the metal that ceases as soon as the limit of the vacuum is attained. When the mercury reascends into the bulb, B, the orifice, a, closes and the air is driven into the reservoir, M. It is the tubes, G and E, then, that replace the cocks.

The tube, E, presents at its upper part a bulb, F, de-

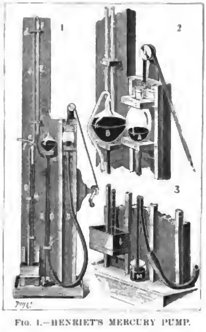

FIG. 1.—HENRIET'S MERCURY PUMP.

signed to prevent projections of the mercury, which can never enter the apparatus in which a vacuum is forming, since the tube, J, is bent at the base at e, so that the mercury falls into the barometric tube, H.

This tube, H, is designed to measure the pressure in the apparatus. It is beveled off at the lower part so as to permit of the introduction of gas into the pump without any projection of the mercury taking place. From the bulb situated at the top of H starts a tube formed of two equal parts—one of glass and the other of rubber. The rubber one permits of forming a partial vacuum by means of a shower bellows. The operation finished, a movable reservoir, I, receives the tubes, O and H, both of which dip into the mercury. The rubber tube offers no opportunity for leakage, since, when a vacuum exists in the pump, it is completely filled with mercury.

A rod fixed to the base, and not represented in the figure, permits of holding a test glass in the reservoir, M. It will be seen that every detail has been carefully looked after in this pump, and that it is possible, in fact, to prevent all those leakages that are so apt to occur in the ordinary apparatus of the kind.

M. Carlos Alban has recently devised a pneumobarometric pump that permits of quickly obtaining a satisfactory vacuum within a given space.

This apparatus, which is represented in Fig. 2, consists of a bottle, E, with three tubulures (No. 1), and of a barometric tube, T, terminating at the top in a bulb, A, the details of which may be seen in No. 2. This bulb is provided with two cocks, R and S, and a pressure gage, N. The apparatus as a whole is fixed to a board that carries in the center, movable around a horizontal axis, a pivot support which may be placed upon the edge of a table. It is therefore possible for the apparatus to assume both a horizontal and vertical position.

In order to form a vacuum, dry and boiled mercury is introduced into the bottle, E, in sufficient quantity to allow the bulb and barometric tube, when the apparatus is placed horizontally, to become filled, and enough mercury to remain to cover the lower aperture of the tube, T.

A vertical position is first given to the apparatus, in order to cause the mercury to descend, and after this it is gently brought to a horizontal one. The tube and then the bulb become filled with air, which escapes through the cock, S. The latter is then immediately closed. The apparatus is next placed in a vertical position again, the bulb remains empty, and upon opening the cock, R, it is possible to read upon the pressure gage the degree of vacuum obtained.

The cock, R, is afterward closed and the same operation is repeated until a vacuum of 1 or 2 mm. is formed. A bottle, O, placed at the upper extremity of the tube, is filled with phosphoric acid in order to absorb the aqueous vapor. An equilibrium is soon established in the two branches of the pressure gage, and we then have a barometer that may be utilized.

It is easy with this apparatus to repeat different vacuum experiments. The upper extremity of the tube, T, is connected by rubber with the apparatus in which the air is to be rarefied. Upon the cock, R, being opened, the air is sucked in and then introduced into the bulb, A. The cock, R, is then closed, the apparatus is placed in a horizontal position, and the air is driven to the exterior through the cock, S.

The apparatus, which is 5 ft. in height and 3 in. in width, is very easily manœuvered. With it, it takes but a very short time to perform various experiments, such as forming a vacuum in a Geissler tube, causing a jet of water to play in a vacuum, etc.—La Nature.

THE LOWER CONGO AND ITS PEOPLE.

FROM Banana to Boma the country is flat, and in the rainy season very swampy, the banks are thickly

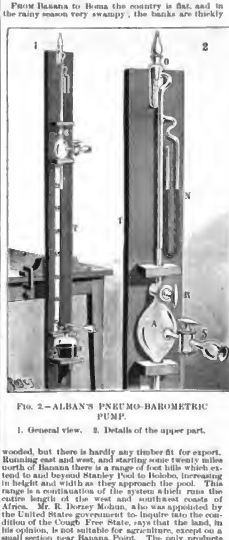

FIG. 2.—ALBAN'S PNEUMO-BAROMETRIC PUMP.

1. General view. 2. Details of the upper part.

wooded, but there is hardly any timber fit for export. Running east and west, and starting some twenty miles north of Banana there is a range of foot hills which extend to and beyond Stanley Pool to Bolobo, increasing in height and width as they approach the pool. This range is a continuation of the system which runs the entire length of the west and southeast coasts of Africa. Mr. R. Dorsey Mohun, who was appointed by the United States government to inquire into the condition of the Congo Free State, says that the land, in his opinion, is not suitable for agriculture, except on a small section near Banana Point. The only products of the soil shipped to Europe are palm kernels, palm oil and peanuts; and these are the only articles which are traded for by factories in the Lower Congo Valley. A few vegetables are grown in the gardens attached to each factory, but the soil has to be worked over and over again and watered two or three times a day in order to make them grow. No domestic animals exist among the natives, except a few goats and sheep, which command high prices. All the beeves, which are consumed by the railroad company's employes, are brought from Benguela and Mossamedes (on the southwest coast in Portuguese territory) by the Compagnie du Produit du Congo, which has established a large cattle ranche on the island of Mateba, below Boma. There are about 3,000 head there, and this herd is increasing. The tsetse fly does not exist, and the land is such that it could, no doubt, be made to yield profitably without an enormous sum being expended for irrigation. It is possible that on the hills to the north of Banana coffee might be grown advantageously, and cocoa on the lowlands; but the experiment has not yet been tried. The articles used for trade with the natives are red bandana handkerchiefs, gin, cloth, beads, machetes, old silk hats, colored parasols, cheap knives, flintlock muskets, powder, brass rods, crockeryware, tinware, old uniform coats, rum and watches. All these articles are speci-

ally made for the trade, and the standard of value is a piece of handkerchief 24 feet long and 3 feet broad, and valued at about 2s. 6d. When the trader buys produce he gives out cards to the natives which are good each for a piece of handkerchief, and when the caravan has been bought out the natives come to the store and hand in their cards, where they can select what they want to the value of the cards held. As a rule they will not touch money, regarding it as useless; and this, of course, is a great advantage to the trader, who makes large profits in exchange for handkerchiefs, which probably cost him, landed on the Congo, duty paid, about ten pence each. The quantity of gin which comes into the Congo is enormous, but none of this ever reaches the interior of the state, as its importation has been prohibited. Very little ivory is bought in the Lower Congo, and this comes from a distance of not more than 100 miles north, south or east of Boma and Matadi. The large quantities of ivory which are being shipped from the Lower Congo come entirely from the Upper Congo. These shipments are increasing year by year, and Mr. Mohun gives it as his opinion that there is ivory enough in Central Africa to last at least another century. The natives of the Lower Congo belong to the Fiote tribe, but there is absolutely no king or chief among them. There are some so-called kings; but they have no authority whatever and are only kings because they call themselves so, on account of having a few more rods, bales of cloth or boxes of gin than their neighbors. Each village is independent of the other and it has its own head man, but no one recognizes the right of any one as their supreme ruler. Fetichism is largely practiced, and there is much quiet poisoning going on in the different villages by fetich doctors, but the hanging of several of these poisoners by the state has had a most salutary effect upon the remainder. They practice no religion whatever; they worship no idols, no fire, sun, or moon, or stars. If they wish to accomplish something, they propitiate a wooden fetich by hanging beads and gin bottles about its neck and murmuring some jargon to it. If something is stolen from them, they drive a nail into the fetich, perfectly convinced that in this manner they will succeed in killing the thief. Near Boma there is a native school of medicine, and the people who attend it for study are called "Inkimbas." During their term of study they must keep themselves whitewashed or painted white from head to foot. The natives are not particularly savage or vicious toward the white men. Only once in a while has the state found it necessary to send expeditions to enforce the laws. They have no arms of their own manufacture, and for hunting and war purposes use the trade flintlock musket. When a native dies and is buried, if he is a rich man, his body is wrapped in hundreds of yards of cloth, and many pounds of gunpowder are fired over his grave, which has been covered on the top with empty gin bottles, demijohns, basins and pitchers; at the head a large red, blue and white umbrella is stuck in the ground and hoisted. At night his friends and family indulge in a dance and drunken orgie. Their hair is usually dressed in some fantastic fashion; on their legs and arms they usually wear large brass rings, and around their necks a necklace of beads or tin tags from packages of tobacco. Their only clothing consists of a breech clout, or piece of cloth tied round their loins; no head covering whatever. Their food consists principally of palm nuts, palm kernels, manioc and bananas; also rats, chickens and locusts. They are not a particularly strong or healthy people, their only strength lying in their legs; and it is very rare to meet one who has reached the age of fifty years, although many look a hundred years old. A great number die of pulmonary complaints.—Journal of the Society of Arts.

STATURE OF MEN OF GENIUS.

HAVELOCK ELLIS has been tabulating the measurements of height of 290 men of genius of all lands and ages. His idea is to find out whether the facts bear out the theory often stoutly urged that great men are apt to be short men. His conclusion is that they are apt to be either above or below the medium height. In the lists that he has compiled (Nineteenth Century, July), 113 of the men included fall into the list of tall men, 110 into the list of short men, and but 57 into the list of men of medium height. This medium height he places at from 5 feet 4 inches to 5 feet 9 inches. He does not claim accurate knowledge of the height of more than a small proportion of those whose names are included in the lists, classifying many by the mere description of tall or short as furnished by their contemporaries, precise figures not being obtainable. The results tally, however, with those derived from other sources, and furnish, Mr. Ellis thinks, a fairly safe basis for general conclusions. Among some of these conclusions, as drawn by him, we quote the following:

"It is clear that the belief in the small size of great men was not absolutely groundless. There is an abnormally large proportion of small 'great men.' It is mediocrity alone that genius seems to abhor. While among the ordinary population the vast majority of 68 per cent. was of middle height, among men of genius, so far as the present investigation goes, they are only 23 per cent., the tall being 41 per cent., instead of 16, and the short 37, instead of 16. . . .

"The final result is, therefore, not that persons of extraordinary mental ability tend either to be taller or shorter than the average population, but rather that they tend to exhibit an unusual tendency to variation. Even in physical structure, men of genius present a characteristic which on other grounds we may take to be fundamental in them; they are manifestations of the variational tendency, of a physical and psychic variational diathesis. In a slight and elusive shape, a shape so elusive that it is rarely hereditary, the man of genius represents the same kind of phenomenon which, in organic nature generally, appears to have slowly built up the animated world we know. Just as the visible world is the outcome of the accumulated gross variations of plants and animals, so the world of tradition and culture is the outcome of the accumulated delicate variations of men of genius. The product is different, but it has been obtained by the same method.

"It would be interesting if we could trace in a more detailed and precise manner the factor of physical stature in the constitution of the genius variation, and ascertain its precise significance. This is still difficult. One or two points may be noted.

"It must be remembered that genius, however it may be defined, is certainly only an excessive development of characteristics which may be traced in much more rudimentary forms. It is thus not impossible to throw light on the subject of genius by investigating the peculiarities of physical stature generally, and the common intellectual accompaniments of underdevelopment and overdevelopment. The conclusion we have reached, that both tall and short individuals tend to predominate unduly among persons of genius, is confirmed and to some extent explained by observation of the general population. The observations so far made, indeed, are few, but so far as they go perfectly definite. Thus Mr. Bohannon—who, under the inspiration of Prof. Stanley Hall, has collected data concerning over one thousand abnormal children in the United States, dividing them into various groups according to the predominant abnormal character—finds that both tall children and short children are intellectually superior to children of medium height. The tall (except in cases of very excessive tallness, which may be regarded as pathological) showed their superiority both in general health and mental ability; at the same time they were notable for their sensitiveness, good nature, even temper and popularity with others. The small were less often healthy, and consequently were apt to be delicate, ugly or vicious; but when fairly healthy they tended to show very great activity both of body and mind. . . .

"It would still remain to show the causes of this tendency; for it is scarcely possible to hold that the health and ability of the tall is due (as has apparently been suggested) to forced association with their elders in youth, and quite absurd to hold that the activity and mental quickness of the small is due to the arrested development caused by forced association with their juniors. In both cases it seems probable that the primary cause is a greater vital activity, however we may ultimately have to define 'vital activity.' Among the tall such intensity of vital action has shown itself in unimpeded freedom; in the short it is impeded and forced into new channels by pathological or other causes. The latter case is perhaps the more interesting and complicated. An anthropometric examination of short men of genius would throw much light on this question. There are certainly at least two types of short men of genius: the slight, frail, but fairly symmetrical type (approaching what is call the true dwarf), and the type of the stunted giant (a type also to be found among dwarfs proper). The former are fairly symmetrical, but fragile; generally with little physical vigor or health, all their energy being concentrated in the brain. Kant was of this type. The stunted giants are usually more vigorous, but lacking in symmetry. Far from being delicately diminutive persons, they suggest tall persons who have been cut short below; in such the brain and viscera seem to flourish at the expense of the limbs, and while abnormal, they often have the good fortune to be robust both in mind and body. Lord Chesterfield was a man of this type, short for his size, thickset, 'with a head big enough for a Polyphemus.' Hartley Coleridge carried the same type to the verge of caricature, possessing a large head, a sturdy and ample form, with ridiculously small arms and legs, so that he was said to be 'indescribably elfish and grotesque.' Dryden—'Poet Squab'—was again of this type, as was William Godwin; in Keats the abnormally short legs coexisted with a small head. The typical stunted giant has a large head; and such stunting of the body has, indeed, a special tendency to produce large heads, and therefore doubtless those large brains which are usually associated with extraordinary intellectual power. It is a curious fact—as a distinguished anatomist, the late Sir George Humphrey, remarked many years ago—that when from any cause the growth of the rest of the body is stunted, the head not only remains disproportionately large, but often becomes actually larger than in ordinary persons. 'Thus short persons and persons with imperfectly developed lower extremities are not uncommonly remarkable for the size of their heads, as though the expenditure of growing force being too great in one direction, other parts are ill cared for.' It may be added that the commonest type of dwarf possesses a proportionately large head and short legs.

"It would doubtless be an attractive task to attempt to trace the causes which lead genius to be associated at once with both abnormal extremes of stature. It must probably be found at an early period of embryonic development, when, as we know from the researches of Dareste and others, the causes of dwarfism may also be found, sometimes in arrest of growth resulting from precocious development. Here, however, it is enough to have ascertained the facts in a roughly approximate fashion. It need only be pointed out, in conclusion, that the result we have reached, although apparently new, is such a result as should have been expected. Geoffroy Saint-Hilaire long since, and Ranke more recently, have pointed out that both giants and dwarfs—the abnormally tall and the abnormally short—are usually abnormal in other respects also. From the biological point of view we know nothing of 'genius,' what is so termed being simply an abnormal aptitude of brain function; so that among those variations and abnormalities which, as is already generally agreed, we find with unusual frequency among the very tall and the very short, extraordinary mental aptitude ought sometimes to occur."

ECHINOCYSTIS LOBATA—HARDY ANNUAL.

ECHINOCYSTIS LOBATA.

THIS is an annual trailing plant, which will not find favor with those who love brightly colored flowers, but the elegance of its habit will commend it to others. It is a cucurbit native to the Northeastern States of America. The plant is nearly glabrous, with slender, angular stems, palmately lobed leaves, branching tendrils, and male flowers in branching panicles, the female flowers solitary, shortly stalked, from the same axil as the male flowers, and ripening into an ovoid greenish berry studded with small prickles. We are indebted to the Gardeners' Chronicle for the cut and copy.

RENEWING OLD TREES.

OLD trees are among the most cherished treasures of rural and suburban homes. They are the most costly, too, as every finished product is costly into which has entered those transforming and creative processes which only long reaches of time can furnish. An old house may fall down or be destroyed by fire, and while we mourn the loss of the visible sign of old associations, a better and more beautiful structure can be made to take its place. But when an old tree that has been the

guardian of the home for generations, and stood there before the home was founded, surrenders to the blast, the loss is beyond repair, for a long time, at least. As there is no immediate remedy possible, the need of precaution becomes all the greater. When one of these old sentinels begins to show signs of disease and decay and year by year grows more attenuated in its branches and weaker in leaf growth and power, we watch it as we watch a friend attacked by a slow but incurable malady. But remedies are now being discovered for almost every ill of the body, and successful tree surgery is or may be as common as the higher form of that science. A recent number of Garden and Forest discusses the rejuvenescence of old trees, and gives practical directions for effecting it. Directly to the point are two illustrations of the same tree, a venerable oak in the Arnold arboretum. The first is of a tree with far reaching branches, but marked by infallible signs of decrepitude, the leafage scanty and the general prospect of life discouraging.

The second illustration shows the same tree twelve years later, shorter of limb, it is true, but displaying vigor in every leaf and fiber, and exhibiting every characteristic of youth and strength and hopeful promise of longevity. No miracle, not even one of Nature's, has been performed. The result is simply one of skillful tree surgery, of intelligent pruning according to the De Car's system, which, instead of sending the tree blood long distances through collapsed and withered arteries, contracts the area and applies the nourishing forces in such a way that they can be assimilated and made to promote the growth of all the members. The process is one which almost any intelligent farmer or tree owner should be able to apply. "Vigor can be restored to a tree in this condition by shortening all its branches by one-third or one-half their entire length. The only care needed in this operation is to cut back each main branch to a healthy lateral branch, which will serve to attract and elaborate by means of its leaves a sufficient flow of sap to insure the growth of the branch." These directions must be carefully observed to prevent further decay, and care must also be taken to leave the lowest limbs the longest, so that the greatest possible leaf surface shall be exposed to the light. So if some old tree, near roadside or dwelling, that has been the landmark of a century, shows alarming symptoms, the owner should not despair before he has treated it according to the general plan here laid down.—Boston Transcript.

TOBACCO IN GERMANY.

THE consumption of cigars is steadily increasing in Germany, whereas the use of the old clay or porcelain pipes is steadily decreasing. In the cigar manufactories of Baden alone 1,000 to 1,200 more workmen were engaged last year, and it is said at the same time that the goods stored in 1895 have also been disposed of; the demand at times was greater than the production. Through the increase of cigar factories, there is a growing stock of raw tobacco for pipes. But while the cigar is driving out the pipe of the German middle classes, the laborer and the peasant, on the other hand an enemy is arising for the cigar in the cigarette and short pipe, the use of which has been imported into Germany from England.

The consul-general at Frankfort says that the German manufacturers of cigarettes look upon the constantly increasing use of foreign cigarettes in Germany with much uneasiness. The import, which in 1895 was only 44,900 kilogrammes (98,780 lb.), advanced to 161,800 kilogrammes (355,960 lb.) in 1895, and 171,700 kilogrammes (377,740 lb.) in the first eleven months of 1896. It surpasses the value of the German export of cigarettes already six times, and is at least half as large as the value of the cigarette manufacture in all Germany. France is sending large quantities of cigarettes each year, and the imports from Turkey, Greece, and Herzegovina are also increasing. It is stated that the importation of English smoking tobacco might be increased, and it is already slowly but steadily gaining ground. At Frankfort a great deal of English tobacco is smoked, especially by the upper classes.

It is Consul Oppenheimer's opinion that English tobacco and pipe manufacturers might with advantage open business connections in many places in Germany. The wooden pipes which of late have almost entirely ousted clay and porcelain pipes are indeed manufactured a great deal in Germany, but they are finished in England, especially the better qualities (silver mounted), and these find a ready market.

Considerable attention has lately been given in Germany to innovations in the culture of tobacco. The tobacco plant has been known in Europe for three centuries, and during the same period its culture has been an annual one. The seed is sown in hot beds, brought to germination there, and when the young plants have grown somewhat, they are transplanted into open soil in order to be harvested when the valuable leaves have developed. This culture is based upon the idea that the tobacco is an annual plant and cannot outlive the winter, so that it must be sown annually, and be planted afresh every year. Now it is said that tobacco planters and botanists have been mistaken.

Wilhelm Darocsi, of Budapest, the editor of a Hungarian tobacco journal, has proved that tobacco is a perennial plant, which may be kept in full vigor for years, and that it then has fresh leaves every year. Should these leaves in the second year and later on prove of use for smoking material, this discovery will bring about the possibility of saving the tedious and expensive method of growing seedlings every second year or oftener, and doing away with their planting in the open fields, and thereby of reducing the cost of production of tobacco very considerably. Whether this will be applicable also to the German climate cannot yet be asserted without trial.

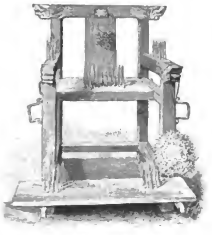
Two German tobacco manufacturers have also kept tobacco over winter as decorative plants, and one of them is even in possession of a plant aged seven years. Both are of opinion that these perennial plants only [illegible] diminutive leaves, so that the value of [illegible] over winter is but trifling, regarding them [illegible] point of view of leaf tobacco. [illegible] is of a different opinion in this respect. [illegible] to his views these small leaves are only a [illegible] of the unfavorable climate, perhaps the [illegible] also with the kind of plant which had been [illegible] to stand over the winter; at all events he says that he obtained good useful leaves even in the second year's crop in Hungary.

Though in this respect the importance of the discovery may be doubtful for the culture of tobacco, the observers are so far unanimous on one important point, viz., as to the possibility of increasing the tobacco by seedlings from perennial plants. This observation is of the greatest importance; if it is possible by cutting the tobacco plant after the harvest to shield the roots against frost by covering them up, they will, at the beginning of spring, germinate again and furnish shoots which can be planted out. In this way it would be possible to shift the tobacco harvest in Germany into a more favorable season of the year. This may become of importance to the culture of tobacco in such a way that tobacco gathered and dried under more favorable temperature and conditions of humidity would probably be much better in quality than hitherto.—Journal of the Society of Arts.

THE GUIMET MUSEUM.

THE Guimet Museum, which was founded at Lyons eighteen years ago, and afterward ceded to the government, was, in 1888, transferred to Paris and installed in the vicinity of the Trocadero. This public museum, now classed among the national institutions, serves for diffusing information as to the civilizations of the East and for facilitating religious, artistic and historic studies by means of the images and sacred books and of the objects of worship and art that compose its magnificent collection.

FUNERAL MASKS FOUND IN THE EXCAVATIONS AT ANTINOE.



CHINESE ARM CHAIR PROVIDED WITH SPIKES.

We wish at present merely to call attention to a few of the novelties with which its already large collection has recently been enriched.

One entire hall is devoted to documents concerning Egypto-Roman worship. In the excavations made at Antinoë, a city founded in Egypt by Emperor Hadrian, and under the ruins of a granite temple that had been pointed out to M. Guimet, M. A. Gayet found half of a statue of a Roman Isis. Exploring, in addition, the ground comprised between the city and the Arabic chain, the learned Egyptologist discovered the site of four cemeteries of different ages. Although the Egyptian, Byzantine and Coptic necropolises yielded up to him only objects of which museums already have specimens, the Roman necropolis, on the contrary, held a surprise in store for him. An entire humanity, an entire civilization, arose therefrom in the form of human remains, now draped in the Roman style and now clad in Asiatic robes. The fabric of these garments, which were Oriental silks woven by Syrians who were experts in combining shades, flowers and symbolical animals, are marvels of color and design. There were also fine women's leather shoes—real Cinderella slippers, stamped in gold with ornamental dies. The majority of the bodies had upon the face a plaster mask (see accompanying figure), provided with enamel eyes and constituting a true portrait. Among the finds we may mention a small convex mirror, not of metal, but of glass backed with mercury. For the history of science and industry, this is a very unexpected and important relic.

In hall No. 7, devoted to the religion of the Parsees or Guebres (adorers of fire and followers of Zoroaster), a very interesting number is a reconstruction of a religious ceremony. A large glass case incloses a group of four figures of natural size—two Mazdean priests and a young man and young woman. The officiating priest, who is of the Rasmic sect, is seated upon the floor with his legs crossed, and is placed in such a position as never to have his face turned toward the north. He wears the "pagri," a sort of high cap, which, like the rest of his costume, is white. His mouth is concealed behind a "padam," conformably to the doctrine of Zoroaster, which regards the saliva, breath, etc., as impure. The other priest, who has a long beard and stands to the left, belongs to the Kadimie sect. He is clad in an ample "jama," girded with the "pichori," and wears upon his head a sort of turban called a "phenta." The young man wears a tunic called a "dougly," and a pair of red silk trousers and a black "pagri." The costume of the maiden consists of a pale rose colored tunic called a "sari," a girdle ("kusti"), a head band ("mathabana") and a sacred chemise ("sudra"), an essential part of the Zoroasterian livery.

A PARSEE RELIGIOUS CEREMONY.

The metallic utensils, arranged upon the low table before which the priest sits to celebrate the office of the Yacna (offerings to the sacred fire), are thirteen in number: The "mahrou," serving as a support for the "barsom," a bundle of date twigs, the "kavan," or mortar, in which the "haoma" is brayed; saucers, or "thaste," one of which contains a ring surrounded by a hair of the sacred bull; and vessels for the sacrificial fire, which must not be confounded with the sacred fire, which is always shut up, out of sight, at the back of the sanctuary.

The Guimet Museum alone owns a complete collection of such utensils, which, like the costumes of the figures just mentioned, are absolutely authentic.

Among the curiosities in one of the halls may be seen an arm chair from Amoy—a terrible instrument of voluntary torture, of which the seat, back, arms and foot rest are studded with sharp points. It ap-

pears that there are fanatics who allow themselves to be carried in this in processions, and, in addition, inflict upon their flesh numerous blows with a ball bristling with iron spikes.—L'Illustration.

THE UNIFICATION OF TIME.*

TIME reckoning, as at present conducted, presents curious anomalies. The civil day begins at midnight and ends at the following midnight. The nautical day begins at preceding noon and concludes at noon of civil day. The astronomical day begins at noon and ends at the following noon. It is therefore apparent that any given date extends over, or into, three different days. Many navigators, however, for many years past, have for convenience kept civil time at sea, redating their logbooks from midnight. A movement to reform time reckoning had its origin on the American continent, from the circumstance that the embarrassment of many independent reckonings had been most powerfully felt in the United States and Canada, those lands of magnificent distances, and that hold within themselves and between their bounding oceans so many degrees of longitude. It is stated in the last report of the Royal Society of Canada dealing with this subject that so late as 15 years ago there were between the Atlantic and Pacific no less than 70 different standards of time referred to in the working of the different railways quite unrelated to and independent of each other. It would necessarily result that as steam and electricity would open the continents of Asia, Australia, and Africa, not to mention the continent of Europe, the difficulties felt on this continent would be further extended.

The movement to effect a reform in the time reckoning of all nations took its origin in Canada in 1876, and therefore as to age it has attained its majority, but not yet its entire fruition. The Canadian Institute was probably the first scientific society in any part of the world to give the subject earnest consideration. At the meetings of this society held in February, 1879, the reckoning of time and the establishment of a prime meridian as a general time zero to be common to all nations was fully discussed. In May and July, 1879, and in May, 1880, the Governor General of Canada brought the views promulgated by the Canadian Institute to the notice of the imperial government, and through the imperial government the attention of foreign powers and scientific societies in all parts of Europe was directed to them. At a meeting of the American Society of Civil Engineers held in Montreal in 1881, Mr. Sandford Fleming (now Sir Sandford Fleming), a Canadian member thereof, led a discussion in formulating certain principles as to reckoning and unification of time.

An active interest in the subject was awakened among the members of this society, many of whom were intimately associated with the great railways of America. An important outcome was the general adoption, a few years afterward, of the system of standard time by which the confusing multiplicity of standards, previously in use, were abolished, and the reckoning by the meridian of Greenwich as the prime standard throughout the United States and Canada. In this consummation the American Meteorological Society heartily co-operated. The Canadian Institute and the last named society sent Mr. Fleming to Venice to attend the International Geographical Congress held in September, 1881; his special mission was to advocate the establishment of a first or prime meridian to be common to all nations as a time zero. The United States and Canadian delegates, among other things, suggested that an international conference should be specially convened to determine upon such a zero meridian, and proposed that such a conference should be held at Washington. The Congress of the United States thereafter, with a view to the principle of uniformity and simplicity of time, passed a resolution in the direction of obtaining an international agreement regarding time reckoning, and thus sought to minimize the difficulties arising from the confusion that then prevailed, and which still, to some extent, continues to prevail. The representatives of 25 nations, as well as the Canadian representative named above, met in Washington in 1884, at the invitation of the President of the United States, and after a conference extending over a month passed seven resolutions, the first five of which have been practically and generally accepted by the civilized world. The observations which follow have a special bearing upon the sixth resolution of that remarkable conference, which was carried unanimously, and is as follows: "That the conference expresses the hope that as soon as may be practicable the astronomical and nautical days will be arranged everywhere to begin at mean midnight."

It is also evident that as the nations which publish ephemerides prepare them four or five years in advance, and as it is important that any date upon which the new era shall commence be one easily remembered by astronomers and computators or navigators, a common understanding should not be delayed beyond the first year of the coming century or 1901.

The question of time reform remained in this position until the year 1893, when the Astronomical and Physical Society of Toronto, in co-operation with the Canadian Institute, appointed a joint committee, with Sandford Fleming as chairman, to suggest the best means of ascertaining the views of astronomers throughout the world. This committee accordingly, upon April 30, 1893, addressed by circular letter the following question to astronomers and other scientific men throughout the world:

"Is it desirable, for all interests concerned, that on and after January 1, 1901, the astronomical day should everywhere begin at mean midnight?"

The replies received were in number 171, of which 108 were favorable to the change and 63 unfavorable. Many of the former are strongly and earnestly in favor of the adoption of the civil day for astronomical purposes, while the writers of some of the latter seem to have been under a misapprehension. They object to the adoption of the civil day on the ground that its division into two series of 12 hours, designated A. M. and P. M., would be inconvenient for astronomers. It is obvious that this objection has no weight, as the 24 hour notation would remain associated with astronomical reckonings as at present; moreover, indications are not wanting that the astronomical practice of counting the hours in a single series from 1 to 24 will gradually win its way into general favor in civil life. The 24 hour notation has already been introduced into use over wide districts in Canada, in several European nations, and throughout the Indian empire; and there is a movement in Europe, in Australia, as well as in the United States of America, especially among railway men, to bring this mode of reckoning the hours into general use.

In classifying the replies from astronomers according to the countries from which they have been received, the votes for or against the change stand as follows:

In Favor of the Change.

Austria	Australia	Belgium
Canada	Colombia	England
France	Greece	Italy
Ireland	Jamaica	Madagascar
Mexico	Roumania	Russia
Scotland	Spain	United States

Unfavorable to the Change.

Germany	Holland
Norway	Portugal

Classifying these results according to the shipping of the different countries represented, we find that those favoring the change represent 85 per cent. of the tonnage of the world's marine. This fact has an important bearing upon the whole question when the convenience of the navigators, with whom the "Nautical Almanac" is a vade mecum, is considered.

This report was communicated to His Excellency the Governor-General, for transmission to the British government, by whom it was finally referred to the Admiralty. The Lords Commissioners of the Admiralty, under whose supervision the "Nautical Almanac" is published, expressed their willingness to sanction such alterations as may be necessary to effect the change at the beginning of the new century, provided other nations who publish astronomical ephemerides are prepared to take the same action. The British government thereupon instructed Her Majesty's representatives to ascertain the views of the foreign governments to which each was accredited, with regard to the proposed change. Of these nine powers, six have formally given their ascent to the proposed change.

The six nations formally assenting to the adoption of the recommendation of the Washington Conference on January 1, 1901, are Austria, Brazil, France, Great Britain, Mexico and Spain. Of the remaining three, Germany and Portugal have not, so far as is known, sent any reply. A brief communication has been received from the Secretary of State at Washington, simply stating that "the members of the United States Naval Observatory are adverse to the 'Canadian proposition,' as they term it, and, at the same time, he sends a copy of the adverse report, signed by these three members."

This is the only report from astronomers and observatories the world round which is of a negative character, and it is the more extraordinary as it also negatives the position taken by the United States from the inception of the movement to reform time reckoning. That country has been in the very forefront of the project; it has, in fact, borne its standard and spread its banner. Its government, its learned societies, its scientists, its practical men, its railway managers, its people, have been at the very cradle of time reform, have carefully watched its adolescence, have rejoiced at its coming vigor; but now in its twenty-first year the Washington Secretary of State has been advised to refuse its adoption. Verily, this child of the Washington conference, introduced into public notice in 1884, by five distinguished delegates as nominated by the United States government, and hailed with the acclaim of 25 nations and Canada, constituting that conference, has had that mark of paternal preference, the coat of many colors, torn from him, and he stands denuded, if not, indeed, wounded, in the house of his own friends.

So far these remarks have dealt with the efforts made by the Canadian societies for the unification of the astronomical and civil day, but the proposition of the Washington conference went further. It sought to bring also into harmony with these two a third discordant note, that of the nautical day. But thus far it has been, only historically but not effectively, a voice—vox sed preterea nihil. It is comparatively easy to obtain opinions of astronomers, as they are for the most part attached to observatories or their addresses are known; but navigators pursue their calling under such different circumstances, being either at sea or for a very short time in port, and then being much occupied with the active duties of their profession. It, however, by no means follows that shipmasters are indifferent to this subject, which so much concerns their business and convenience. In order to reach the opinions of British and foreign shipmasters on this subject, communication was opened by the Astronomical and Physical Society of Toronto, with Mr. W. Nelson Greenwood, F. Imp. Inst., of Lancaster, England, the compiler and publisher of certain kindonometric or tide tables issued at Manchester, England. The result was that Capt. Greenwood propounded the following questions to shipmasters:

1. Are you in favor of the Greenwich meridian being universally recognized as the prime or first meridian by all?

2. Are you in favor of the unification of time as reckoned from such prime meridian and extended to all nations irrespectively?

3. Are you in favor of the unification of time as applied to the civil, nautical and astronomical days; and is it desirable in the interests of all concerned that such days should commence at mean midnight?

4. Are you in favor of reckoning the days by the 24 hours' system, counting the hours for each civil, nautical and astronomical day from mean midnight throughout the 24 hours to midnight again? This will do away with the old A. M. and P. M., but will make mean noon the twelfth hour for all three systems of time reckoning alike.

As question 3 affects more directly the subject bearing of this paper, I confine myself to that.

The result was that, up to July 25, 1896, 409 shipmasters from steam vessels and sailing vessels, both British and foreign, were heard from, and of these 399 answered "Yes" and 10 answered "No" to above question 3. Of these, 363 were masters in active service, representing a total tonnage of 455,810.

There would, therefore, appear a very large amount of unanimity throughout the nations of the world for the proposed changes, but yet there was not absolute unanimity; and to the communication from the joint committee of the Canadian Institute and the Astronomical and Physical Society of Toronto forwarded through the office of His Excellency the Governor General to the Lords Commissioners of the Admiralty, a reply was received in December, 1896, that inasmuch as unanimity in the effort to make the desired change on the part of other nations that published ephemerides had not been obtained, their lordships had no intention of moving in the matter.

In many most important matters involving the welfare or convenience of mankind and in which consent is necessary, a minority—even a small minority—exercises a controlling power. This is one of these matters. But it has not been allowed to rest. The importance of the subject demanded further movement, and that movement in the straight line of a more widespread knowledge and of a continued and (if possible) a clearer presentation of the advantages of the proposed reform.

At the last meeting of the American Society of Civil Engineers, in June, 1897, a resolution was formed authorizing and requesting the board of directors of the society to take such steps as they may deem advisable to move the United States government to finally adopt the sixth resolution of the Washington Conference in 1884.

It is expected that the American Meteorological and other societies in the United States will take similar action. On June 25, 1897, the Royal Society of Canada, at its meeting in Halifax, Nova Scotia, passed the following resolution:

"That as there is a reasonable prospect of the United States accepting the recommendations set forth in the sixth resolution of the Washington Prime Meridian Conference of 1884, the council be authorized and requested to take such further means as may seem best calculated to secure unity of time reckoning at sea as on land; and with that view a special request be made to the British Association, when it meets in Toronto, to co-operate with the Royal Society and other Canadian societies in influencing Her Majesty's government to adopt the proposed change on the first day of the new century, and to make such alterations as may be necessary on the 'Nautical Almanac' as soon as practicable."

The question of the unification of time is not a new one. In fact, it offers an illustration, on the one hand, of the apothegm that "there is no new thing under the sun," and, on the other hand, furnishes an example of that philosophy which teaches that "the thoughts of men are widened with the process of the suns."

Hipparchus, "the father of astronomy," himself counted the hours from midnight to midnight. He found no difficulty in commencing an observation on one day before 12 at night, and ending it the next day after the same 12 at night. Some modern astronomers, it is said, find this is an insuperable obstacle. They might forget to note the change from one day to another. Ptolemy introduced many errors into science, which the world for many centuries believed were truth, and among his errors introduced the practice of taking noon as the moment from which the hours were to be counted. The present astronomical day is then a relic of the Ptolemaic system. The rest of this false philosophy has long ago disappeared. This part, the only part, still survives. It does not, however, survive because it is the fittest, but because it is not the fittest—upon the Lucus a non lucendo principle. And so it remained until in 1804 La Place sent to Le Bureau des Longitudes a letter in which he proposed to unify astronomical time with civil time by counting the hours from midnight, which proposal they adopted. Nevertheless, La Connaissance de Temps continued, and still continues, to appear in the Ptolemaic method of counting astronomical time. La Place, however, who possessed the instincts of a genuine reformer, in La Mécanique Celeste and in the calculation of his tables employed civil time; and in this was imitated by the other French constructors of tables until Le Verrier put on the old garments of a non-scientific conservatism, and started his day at high noon. After the Washington and Geneva conferences and with their discussions before him, M. Faye, the French astronomer, was reminded that the bureau had, under the influence of La Place, formerly calculated the lunar and planetary tables for Paris mean midnight, but no change was made.

The bureau was consulted in 1894 by the Minister of Public Instruction for France, and on October 19 in that year reported in favor "of the principle of the reform set forth in the sixth resolution of the Washington conference, and advocated by various societies in Canada and in the United States," and favored the adoption in practice, provided that the countries publishing the most important ephemerides took concerted action. The bureau, moreover, took a step further in a most important direction. It officially expressed to the Minister of Public Instruction the decided opinion that unification would not be complete until the civil day should be reckoned, as in Italy and in other countries mentioned, in one series of hours from 0 to 24, and so do away with the old notation of A. M. and P. M. This further reform has been already legalized by an act of the Province of Ontario, 58 Vic., Cap. 11, being "The Definition of Time Act, 1895," which provided that the time referred to in any act of legislature, by law, deed, or other legal instrument, be held to be standard time; and as regards that part of the province lying east of the meridian 87° west longitude, standard time shall be reckoned as five hours behind Greenwich time; and as regards that part of the province which lies west of the said meridian, standard time be reckoned as six hours behind Greenwich time.

And it was further enacted that the hours of the day and night in any locality be numbered in one series up to 24, according to the "24 hour notation" so called. So that in respect to time reform, the Province of Ontario has been doing all she can to stand in the foremost rank. This reform has the support of the highest authority.

Sir John Herschell writes: "Uniformity in nomenclature and modes of reckoning in all matters relating

* By John A. Paterson, M.A., President of the Astronomical and Physical Society of Toronto. Paper read before the British Association, Toronto meeting.

to time, place, weight, measure, etc., is of such vast and paramount importance in every relation of life as to outweigh every consideration of technical convenience and custom."

Mr. Christie, the English astronomer royal, among many other potent reasons in support of the change as affecting astronomy, points out that for spectroscopic and photographic observations of the sun, the day is reckoned from midnight, and the same reckoning would naturally be used by the observer for spectroscopic and photographic observations at night and also in determinations of the places of comets, stars, etc., which he may take in connection with his spectroscopic observations. It would seem passing strange to expect the same observer to change his system of reckoning mean solar time according to the class of observations he is making at the moment. Commodore Franklin, Superintendent of United States Naval Observatory, Washington, in December, 1884, just after the Washington conference, wrote a strong argument in support of the change, and remarked: "It seems to be eminently proper that the nation which called the conference should be among the first to adopt its recommendations."

These deponents are culled at random from a great cloud of witnesses and testify accordingly. For the sake of brevity, I do not call to the witness stand Cleveland Abbe, Burckhalter, Comstock, J. E. Gore Hadden, Garrett P. Serviss, Captain Abney, Lewis Swift, Trouvelot, Dr. Max Wolf, and a host of others. But what are the objections urged in opposition to the adoption of this reform? It is said that for a time confusion would prevail at sea. The evident answer to this is the testimony of navigators themselves, as has been above set forth by Captain W. N. Greenwood. These men who stand on the quarter deck and handle the sextant and the "Nautical Almanac" know whereof they speak, and they have not spoken in ambiguous voces, but loudly and definitely. Are we to hear and to give effect to their evidence, or are we to listen to others who live ashore and think they know better? To this there can be only one answer. The other objection to the change is that it would be inconvenient for astronomers and computers. No doubt the change from the Julian to the Gregorian calendar was an inconvenience, and if that objection had prevailed about the year 1582, and continued to prevail, we would have been now still groping along in the dark and devious ways that Cæsar projected. Whose convenience is to be consulted, that of the astronomer or that of the navigator? The astronomer and the computer are not pre-eminent, and their "Nautical Almanac" is not the end. All these are only means to the end, and that end, in so far as this subject matter reaches, is to facilitate the work of the navigator and to perfect the art of navigation. The navigator was not made for the astronomer, but the nautical astronomer for the navigator. There is confusion now, for in various official publications some portions are given in astronomical time and other portions in civil time; but let this reform be inaugurated, and straightway for the future the wrinkles and creases are smoothed out, and harmony reigns, and the sooner the better, so that the masses of incongruity may not further accumulate.

But it may be said that this reform cannot be made practicable in the year 1901, inasmuch as the ephemerides for that year are now published. That circumstance, however, in no respect affects the principle involved in the question. The wisdom of the reform being established, then the date of its inception is a mere matter of detail and may be left for some mutual agreement to be come to among governments interested. If we once get down to the base rock of the principle of uniformity, then it is a matter of certainty that its inauguration will follow very rapidly. At the same time there is a peculiar fitness in having the resolution of the Washington conference carried out literally, that is, on the first day of January, 1901, and that matter could no doubt be accomplished by publishing a supplement to any ephemerides already published for that year.

All reforms have to overcome a certain callousness of custom before they can be accommodated to the various convolutions and angularities of opinion and convenience. Much deliquescence of dogmatism must result before the current of reform shall run smoothly over the rocks of conservatism and mingle with the broad and ever broadening ocean of knowledge, and thus add a fresh sparkle to the face and form of rainbow-vestured truth.

Our feet almost touch the threshold of the twentieth century, our hands are almost on the latch that opens to us new history. Centralizing, harmonizing and unifying are strongly impressive on the spirit of the times. The ages grow from more to more and old orders change. More facilities, more centralization, more uniformity, more cutting off the rough and raveled ends of merely old customs, old methods, and old forms crowd round about us. Old landmarks shift; like old scaffolding, they are no longer useful; they only mar the outlook of progress, and with many other curious anomalies let this one vanish and a new era of time reform brighten the coming century.

These observations are respectfully, but confidently, submitted with the hope that the British Association for the Advancement of Science will lend its aid in bringing this important subject before the nations of the world for final consideration.

THE OBSERVATION OF METEORS, WITH ESPECIAL REFERENCE TO THE LEONIDS.

DURING the next few years a large amount of attention will be given to meteoric astronomy in general and to the great shower of Leonids in particular. The present may, therefore, be an appropriate time to refer to a few points connected with this interesting branch. It has often occurred to the writer that it would greatly facilitate the comparison of different materials if observers adopted one uniform method of recording meteor flights. Some merely give estimated compass bearings, and a rough guess at the altitude and inclination of path, others give the place and direction according to conspicuous stars near, others simply mark the courses on a map without reading off the individual positions, while others give the R. A. and Decl. of both beginning and ending of every object observed. It would be a great advantage if every one tabulated results according to the latter method. It can easily be done if the tracks, as observed, are penciled upon a celestial globe or star chart, and the positions read off; and this is a much more exact method than describing the flights by stars near which they happen to pass.

Another point is that the accurate observation of meteors demands a considerable amount of practice. It would, therefore, be a most useful preparation for intending observers of the Leonids if they carefully watched the Perseids of August, Orionids of October, and some other prominent displays, and gained a little practical experience of the work. They would find it of material assistance to them, and it would enable the Leonids to be observed more expeditiously and correctly than must otherwise be the case. Accounts are sometimes published of meteoric showers by persons who are reporting a perfectly novel experience, and it is not too much to say that such descriptions are useless as regards many essential details. A perfect novice may of course stand and count the number of meteors visible, and may be capable of describing a star shower in a general way, but he is heavily handicapped when it comes to recording the more difficult features with precision.

What photography may achieve in meteoric work we cannot definitely foresee, but it is quite certain that the proper observation of meteors, as at present conducted, demands the work of a lifetime. A man must watch for meteors all night, and suitably record them, and by day he must analyze the observations and determine the radiant points. The observer need not, perhaps, absolutely isolate himself from all other work; but the meteoric branch is such an extremely difficult one, embracing, as it does, some thousands of streams which exhibit many different peculiarities, that in order to grapple with the subject successfully he must make it his constant care and the object of his earnest efforts and thoughts during many years.

Fortunately the Leonids are to be classed among that description of meteors comparatively easy to observe and record. They leave streaks for a second or two, and from these the directions are to be determined with great facility and precision. It is also a fortunate circumstance that the radiant point is surrounded by the well known stars in the Sickle of Leo. The lines of flight may therefore be readily carried back in the correct directions by projecting a straight wand upon the streaks, and noting their points of convergence relatively to the stars named.

The writer has usually found the radiant very definitely and sharply defined, and it can be readily fixed to within 2° of probable error. But naked eye observation is capable of much more accurate results than this. If, during a pretty active return of the shower, the observer will independently fix the radiant during, say, successive half hours of the night; he will in this way get eight, ten, or twelve positions, from which he may derive the mean place of the radiant to within about ½° of error.

The Leonid radiant is sometimes described as very diffuse; but this is a false effect brought about by two circumstances which, if properly allowed for, would leave a very definite and satisfactory position. One cause of its apparent diffusion is that meteors are attributed to it which really belong to the minor showers in Leo and the surrounding region, of which quite a large number exist. They display similar visible characteristics to the Leonids, and can only be dissociated from them by the exercise of extreme care in noting their directions of flight. In Popular Astronomy, vol. I, p. 298, I gave a list of sixty-eight meteoric radiants situated in various parts of the heavens, and active during the period November 10-15; and in the Observatory, vol. xx, p. 306, a table of seventy-two circum-Leonid showers was published. Those which chiefly affect the determination of the Leonid radiant are placed near δ and ι Cancri, μ and ξ Ursæ Majoris, λ Hydræ and π, λ, τ and β Leonis. The meteors are swift and usually leave streaks. Another contributing feature to dispersed radiation is found in the unavoidable errors of observation. Great care and habitual practice can, however, reduce these to small limits, and it will be found that the radiants derived from accurate materials will be pretty sharply defined.

The probable error in the case of different observers must, however, vary to a considerable degree, for practice cannot equally eliminate inaccuracy from among them all. In catching and retaining correct impressions of meteor flights, natural aptitude exercises an important influence. It is like a game of skill depending upon the eye, judgment and quickness in execution. Really few will excel, while many will only attain mediocrity, and some must altogether fail to acquire the desirable proficiency, even after years of experience.

The horary rate of appearance of Leonids cannot be exactly determined unless the contemporary showers are considered, and their meteors separated from the true Leonids. Many observers count every meteor proceeding from the general direction of Leo as necessarily a Leonid, and thus the horary number is exaggerated. If an inexperienced observer gives 20 as the number of Leonids seen in an hour, the fair inference is that not more than 14 or 15 of them were true members of that system. During very strong returns of the shower this point may, however, be disregarded, for the minor streams can then exercise very little relative influence on the results, and are virtually obliterated by the superabundance of Leonids.

One new feature to be attempted during the ensuing return of the Leonids is to photograph the meteor group of November, 1866, in space, and an excellent ephemeris of its nearly stationary position in Libra and southeastern limits of Virgo, during the first four months of 1897, was given in Monthly Notices, lvii, p. 70-2. Some people will regard the idea as little more feasible than opening a correspondence with the inhabitants of Mars, and certainly there appears very slender prospect of its successful realization. The experiment ought, however, to be tried. Let us support every project which has a possible side to it, for it is quite clear that many things deemed beyond our reach are capable of attainment by persevering efforts and proper means. Novel attempts of this kind, if seemingly chimerical, should not be hastily condemned or necessarily considered as vain labor. Mr. Roberts' photographic search for a transneptunian planet was a novelty, and it proved vain labor; but who will say that it ought not to have been undertaken? The same may be said of Mr. Barnard's similar search for a satellite to the moon. To look for a fifth satellite of Jupiter was decidedly a novelty in these modern times, and yet it proved productive. Let, then, new researches like these have our encouragement; for if they do not always succeed, they stimulate our interest and enthusiasm, and make the science more attractive by imparting to it a welcome freshness and, perhaps, a touch of romance.

As to the practical aspect of the question, it is fair to conclude that the Leonid group of 1866 is too faint an object to be ever impressed on a photographic plate, especially when its distance is so great as during the past spring, for on March 1 this was equivalent to 800,000,000 miles, and not far short of the mean distance of Saturn! In the great meteor storm of November 27, 1885, when the meteors were more thickly congregated than in the Leonid shower of November 13, 1866, Prof. Newton computed that "the space in the meteroid group corresponding to each single, visible meteor was in the densest portion of the group a cube whose edge is 32·8 kilometers, or 20·1 miles." This means one small pebble in twenty miles of space! The degree of illuminating power exhibited by a group of these bodies, separated by such distances, must be infinitesimally small. If any one were to attempt to photograph Tempel's comet (1866 I), on its return journey, the chances of success would be far greater, for though the comet has still to run eighteen months before reaching perihelion, it is nearer to us than the meteor group of 1866, and must be infinitely brighter, as it doubtless represents the richest part of the stream. We must remember that Tempel's comet passed its perihelion on January 11, 1866, while the meteor group reached it ten months afterward; and it is quite fair to suppose that the meteoric train of the comet, at a distance of some hundreds of millions of miles from the nucleus, must be relatively tenuous as compared with that part in the immediate wake of the comet. The meteors may not, however, show a regular decrease in numbers according to distances from their derivative comet, but may probably consist of a series of groups. There is every reason to believe that disruptions of a violent character affect the physical character of comets, and this was well exemplified in Brooks' comet (1889 V), visible, in 1896, at its second observed return, which was seen separated into five portions on August 1, 1889. There is, however, every probability that the meteor cluster of 1866 is some hundreds of times fainter than Tempel's comet; yet even the latter was not visible to the naked eye in December, 1865, or January, 1866, and indeed the object was only followed for a month in telescopes. It might be a good plan to endeavor to photograph the comet first, and then fish for its associated meteor stream; for the easier objects are sometimes capable of leading us up to the discovery of the more difficult ones.—W. F. Denning, in Nature.

THE AMERICAN LOBSTER.

PERHAPS no other inhabitant of the ocean so important from a commercial point of view as the lobster has been so thoroughly neglected by the naturalist, says Self-Culture. History and literature, from old Grecian days up to the present, abound in references to this curious creature; but it was not until there was an industrial demand for information in regard to artificial rearing that science really turned her attention lobsterward.

But two species of the lobster are known to the economic world, the European (Homarus vulgaris) and the American (Homarus americanus). To the latter species we will confine our remarks, as the most interesting as well as the larger of the two.

While it is difficult to determine boundary lines of marine products, it is safe to say that a belt from thirty to fifty miles wide, and extending from a little above the Straits of Belle Isle to Delaware, would include practically every American lobster in existence. Indeed, this territory includes much barren ground, some parts being too deep, others too shallow. Almost any depth from one to a hundred fathoms is deemed promising, but the favorite territory is much more restricted. The largest lobsters are found toward the north of this belt—a fact which some consider accounted for by the northern grounds being the most recently fished from, and therefore less culled over.

One hardly expects to find in the lower orders a species of intelligence comparable in interest with that of higher animals. We rather hope to be entertained by some novel substitute which nature may have provided for intelligence. One interesting accomplishment of the lobster is its ability when frightened to project itself, with almost incredible speed, a distance of twenty or thirty feet directly into its hole, no larger round than its body. When feeding it walks about quite briskly on the ocean bottom, which it seldom leaves from choice. Occasionally one can be dragged to the surface by thrusting an oar or pole into the burrow and then withdrawing it hastily as soon as the inhabitant has seized the offending stick in its strong claws. Usually, however, this method only brings the lobster as far as the mouth of its burrow, where it angely releases its hold. In aquariums each lobster soon finds its individual retreat among the rocks with which the bottom should be provided, and which it invariably retains and defends against all intrusion.

As warm weather approaches, usually during April or May, there is a noticeable movement of the lobster kingdom shoreward, into water but a few fathoms deep. Late in the fall a corresponding inclination toward deep water occurs. The winter fishing is therefore in twenty-five or thirty fathoms of deeper water than the summer. The time of these movements is very largely governed by the forwardness of the season. Lobsters are very sensitive both to cold and light, their bodies being accustomed to the comparatively steady temperature and the obscure light of the ocean bottom. Exposure in captivity to strong sunlight is in a short while fatal to them.

Popular literature has more than once accredited to the lobster mother the same careful attention to her young that the crayfish gives. As a matter of fact, they receive neither care nor attention from her. As soon as hatched they at once scatter and shift for themselves. The hatching is from May to August, the average date varying somewhat with the location and the temperature or climate. When first hatched the

young lobster is less than half an inch long and in its habits totally different from the adult. The first few weeks of its life are spent at or near the surface swimming about, and it is not until after the fifth or sixth moult that it sinks to the bottom, even then less than an inch in length. At this period of its life the lobster is still shrouded in mystery, his long journey to the ocean bottom completely removing him from observation. Until four or five inches long they are too small to be held in the lobster traps, and too nimble to be approached direct. Sometimes specimens two or three inches long are found under stones near the coast, but from the time they sink into the ocean up to this period they are rarely found.

Perhaps at no period of its life is the pugnacious disposition of the lobster more apparent than during the first few days after hatching. Cannibalism, always a characteristic of the species, now asserts itself to a surprising degree and renders it practically impossible to raise young lobsters in an aquarium. Occasionally one of these youngsters will be found feigning death on being meddled with, but this is too uncommon to be regarded as a characteristic even of the young, and is never met with in adults.

In the matter of food the young lobster does not appear to be very discriminating, and seizes upon almost anything of available size with equal avidity. In its mature state the flesh of fish and other inhabitants of the deep is the favorite dish, and it does not seem very particular as to whether this is fresh or not. The bodies of dead fish are seized very greedily. Occasionally vegetable matter appears to furnish a part of their supply. Weak or injured lobsters, too, are the almost certain prey of their stronger and healthier companions. The food is seized and crushed by the heavy claws before entering the mouth. These claws, its dreaded weapons of defense, in the larger specimens frequently comprise more than half of the entire weight and a length seemingly out of all proportion to the remainder of the body. One monster, captured in the Penobscot Bay, Maine, weighing a little more than twenty-three pounds and measuring twenty inches, bore a crushing claw nearly fourteen inches long and more than sixteen inches in circumference. This lobster, it is estimated, could with ease have crushed the wrist of a man.

A most interesting means of defense, or rather of escape, is possessed by the lobster: that is its power, on demand, to cast off an imprisoned limb and reproduce a new member in a few weeks, the greatest inconvenience apparently to the lobster being its increased susceptibility to attack.

The use of the lobster is too well understood to need mention here, and its preparation for market is hardly within the province of the naturalist. Briefly, it may be said that lobsters are baited with dead fish in slat boxes with funnel-shaped entrances at each end. These are lowered to the ocean bottom and from time to time raised and examined. Once fairly caught, a full-grown lobster very seldom regains his liberty. This method, primitive as it may seem, is effectual enough; so much so that year by year the numbers of the lobster and the range of his camping grounds are gradually diminishing. While statistics show rather an increase than a diminution of the number caught, it must be remembered that this is through a constantly enlarging army of fishermen and traps, and is not due to the supply of lobsters. At the same time, as the old warriors of the deep are caught and give place to a newer generation, the weight of the catch is seriously diminished, even though the number is increased. The decline in pounds in the catch between 1887, when 28,882,188, valued at $799,717, were landed in the United States, and that of the previous year was more than 5,000,000 pounds, while the market value was over $260,000 more in the year 1886. More than 200,000 traps were, in 1892, operated, and over $600,000 was invested in the various branches of the business. The importance, then, of protecting the lobster and preserving the industry to future generations is easily seen, while the wholesale destruction to which it is now subjected is a matter for universal regret. WILDER GRAHAME.

ACETYLENE AS A QUANTITATIVE REAGENT.

ACETYLENE may be employed for the determination of copper. The salt to be analyzed is dissolved in 100 to 200 times its volume of water mixed with a few cubic centimeters of ammonia and heated for a short time on the water bath. Acetylene is then introduced into the dark blue fluid to saturation. The precipitate is complete even in the cold, but it takes place more quickly, and is better aggregated on warming, while at ordinary temperatures a portion often adheres obstinately to the sides of the vessel. In a closed flask the precipitate can be preserved for any length of time without decomposition; in an open vessel a part of the precipitate is again dissolved as long as the fluid remains alkaline. The copper acetylide is now collected, washed and decomposed by being digested for half an hour with hot diluted nitric acid, filtered from the carbonaceous residue and the filtrate evaporated to dryness and ignited. The ash of the filter and residue is also taken and the whole weighed as CuO. The separate ignition of filtrate and insoluble residue is advisable to prevent explosion. A too large excess of acid must be avoided. The acid contained in the original copper salt can easily be detected in the filtrate from the acetylene precipitate. For the separation of zinc and copper, as salts of the former metal are not decomposed by acetylene, the method is most useful. In the presence of excess of sulphurous acid the whole of the copper is precipitated by acetylene in a mixture of a solution of salts of the two metals. In an experiment with a known quantity of zinc, it was found that none was carried down by the copper acetylide precipitate.—Pharm. Centralh., xxxviii, 426.

A table has been made of all the degrees which have been granted by Cornell University. The total is 4,304, of forty-seven distinct kinds. Only two granted in 1896 are honorary degrees. There are LL.Ds. It is significant of the great growth of Cornell and its greater present importance in the educational world, that 3,014, or 70 per cent. of the 4,304 degrees, have been granted in the last ten years.

SCENES IN BENARES.

WE publish to-day reproductions of some instantaneous photographs taken by Dr. Borek, of Dresden, during his last visit to Benares, that Mecca of the Hindu, so renowned for its fifteen hundred temples. This city is full of interest to any one who wishes to make a study of the customs of the natives, but he will probably find it difficult to penetrate the barrier they draw about themselves. The Hindu servants and guides will take a stranger about the city showing him temples and things of general interest until he is worn out, but they are seldom willing to introduce him to the real life of their people. If told that the visitor wishes to go to the Ganges early in the morning to see the bathers, they will find some excuse, such as not being able to get boats or boatmen; so that the traveler who finally reaches the sluggish, muddy river later in the day has no conception of the entire change in the physiognomy of the stream when seen in the delightful coolness of the early morning hours when only representatives of the highest classes, rajahs and Brahmins, bathe by the light of the moon or of dawn. Noble ladies and beautiful girls wrapped in light colored muslin stand in the Ganges and pour water over their limbs from their little bowls or "lotas," putting aside the custom of seclusion usually so carefully observed by women in Benares. Each hour brings a lower class of bathers, until only the lowest are seen upon the banks, and this is the time that the smiling guide chooses for showing the river to the European. It is the same with everything he wishes to see. In the temples he finds miserable beggars and Brahmins of low rank, but the doors of all the mysterious "sooms," cloisters and places where those who wish to hide from the Europeans seek refuge as penitents, are closed to him. One of the most interesting of these places is shown in one of our illustrations. This cloister is of historical importance as the hiding place of the last independent rajah who was driven from his palace in the last century by Warren Hastings. He felt safe here among the Shiva idols, the old lingams over which he so often piously poured the sacred water of the Ganges, milk and melted butter, as other penitents now do; for he knew that even Warren Hastings would not ignore the prohibition of the Brahmins by entering their religious retreats. ... "soom" ... are passe... worship of ... gam idols by ... ndus who are ... from Benares as ... yassis, or people

CHILD MURDERERS SPINNING IN THE PENITENTIARY.

voluntarily leave behind them all their worldly property, all that adorns life, to spend the rest of their days under some distant sacred banyan tree as lonely hermits. One of these Sanyassis is shown at the right in the engraving. He will wander away from here to solitude clad only in a cotton cloth, an antelope skin over his shoulder to be used as a bed, a chain of seeds around his neck, on which to count his prayers, and in his hand his "lota." Those who belong to this sect are not allowed staffs until they are more than sixty years old.

Innumerable pilgrims are always traveling to Benares. Many who are sick or dying go there by railroad, in palanquins or ox carts, or on the backs of elephants or camels, so as to die near the sacred Ganges. Death has no terrors for the Hindu who knows that his ashes will be intrusted to the "eternal Mother Ganga." One needs strong nerves to visit the Munikarnika Ghat, or Burning Ghat, as the English call it, especially during epidemics, when hundreds are burned every day. If a Hindu dies in his house, he is wrapped in a shroud of white or yellow, with red spots, placed on a rough bier and carried out, not through a door, but through a hole that is made in the wall, and then immediately closed up again, so that the departed soul shall not find its way back to those that are left. The body is then carried to the bank of the Ganges and is often left where the river can wash it and the sun beat upon it, like the one shown in our engraving. It never occurs to a Hindu that the sacred river can carry contagion. If the sick man dies close by the Ganges, a handful of mud from the river is pressed on the blanching lips, then the body is placed on the bier, dipped in the Ganges and finally packed in the pile of wood or dried cow manure. In building the piles, four strong posts about five feet high are driven firmly in the ground and the pile erected between them, so as to prevent its falling apart when burning. When half of the pile has been laid, the body is placed upon it, the relatives and friends scattering pieces of sandalwood over the body, and then the pile is completed. Then the chief mourner, who must be the son of the deceased, or, in case of the absence of the son, his father or brother, walks three times around the pile and fires it with a sweet smelling torch of sandalwood. After performing this ceremony, he withdraws to have his hair cut. Our engraving shows the chief mourner and the barber on the steps a little above the funeral pyre. After having given expression to his grief

in this manner, he joins the other relatives and together they wait for the body to be reduced to ashes, which are then collected in an earthenware jar and consigned to the Ganges.

The multitudes that flock to Benares from all parts of India are taught that they must respect the English laws or be sent to the central jail or the district jail. These jails are superintended by Europeans who are assisted in the performance of their duties by well behaved convicts. The prisoners have to work at the potter's wheel, in the kitchen, as painters or as blacksmiths, or at other occupations, according to their caste. One of our illustrations shows carpet weavers working in their old fashioned way, drawing the weft threads with their toes while their hands are otherwise employed. It is surprising to see how carefully the English respect the caste privileges even here in the prison. The Brahmins are not only allowed to keep by themselves while at work, but their food is cooked separately by cooks of their own caste. If a Brahmin is to receive a whipping, the cat-o'-nine-tails is used upon him only by a fellow prisoner of equally high caste. Another engraving shows a prisoner leaving his cell to be executed. He was a chief captured in the war against Burma and he defended himself against a keeper who was torturing him—a capital offense!

One of our engravings shows women grinding corn in the prison. Some of these women are clad in white and some in yellow, the latter color indicating that their crimes are serious enough to merit transportation and that they will be carried by the next transport to the Andaman Islands. Each of the women wears around her neck a steel ring to which is attached a wooden pendant bearing the record of her crime and stating the length of time she is to be imprisoned. In the neighboring spinning room there was, when the photograph was taken, a woman dressed in yellow who was to be taken to the islands the next day, because she had killed her two little daughters. The authorities had shown her the questionable kindness of allowing her little son to spend a few hours with her before her departure. Superstition and the inexorable laws of caste made a criminal of this woman. Her caste required her to celebrate the marriage of each daughter with a display far beyond her means, and superstition told her that she would be doing a good deed if she sacrificed the little girls to the elephant-headed god Ganesh, and that as a recompense these two girls would be born again to her as boys; so they were put in a kettle of boiling milk before the picture of this god. Formerly large sums of money were given to Brahmins to induce them to assist in this way in reducing the number of women, which was undesirably large.

It is pleasant to turn from all this misery to the beautiful poppy fields, which are such a rest to the eyes after having looked for a length of time upon the blinding yellow walls of the prisons. The region most celebrated for the cultivation of the poppy and the manufacture of opium lies between Benares and Ghazipur. Our engraving shows a woman cutting the green poppy heads, for which purpose she uses a knife consisting of five blades bound together, while the man who follows her catches the juice in an iron ladle. The overseer watches carefully to make sure that none of the valuable fluid is purloined. Even the water used in washing the wooden moulds in which the cakes are pressed is boiled down, so as to save even the diluted opium.

Dr. Boeck completed his collection of pictures by taking one of himself and the men who served his supper at the Dak Bungalow, where European travelers usually stop. He had proposed before to take their pictures, but, as Mussulmans, they were bound to respect Mohammed's law prohibiting portraits (waiters are always Mohammedans), and therefore refused to sit for him. Now he decided to take an instantaneous picture without their knowledge. While they were preparing the meal he arranged the camera, the flashlights were lighted at the proper time, and their pictures were taken with his own.

BURMAN CHIEF GOING TO EXECUTION.

For the accompanying engravings and the above details we are indebted to Ueber Land und Meer.

A GREAT SOUTH AMERICAN WATER SYSTEM.*

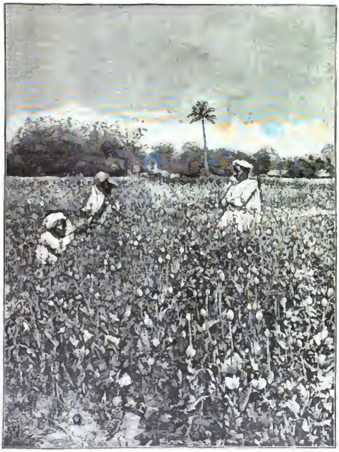
As is well known, the trade winds sweep along the equatorial belt across the Atlantic Ocean from east to west at stated and well-defined periods of the year. On encountering the South American continent they are not detained in their course, as the land is low and extends westward in vast expanses of plains not unlike the Russian steppes or the pampas that form the territory of the Argentine and the other republics that lie toward the extreme south of the continent.

The course of these trade winds is only stopped by the mighty Cordillera of the Andes, which runs along the whole of the South American continent, not far from the coast of the Pacific Ocean. It is on the summit of these mountains that all the moisture gathered by the winds during their long flight is deposited. In some parts the height is such that, notwithstanding the fact that the locality lies in the very heart of the tropics, the moisture crystallizes into snow and melts slowly. In other altitudes it condenses into water and flows downward, forming a series of torrents and streams which precipitate themselves along the mountain flanks, seeking the lower levels.

Two great water systems are thus formed, one toward the south of the equator—that of the Amazon—and another some degrees to the north, and above the equator—that of the Orinoco; the first one the largest river in the world, and the other the third largest stream of water known, since it is only excelled in volume by the Amazon and by the Congo.

The Orinoco is to all intents and purposes an inland sea. Like the ocean, it has calms and tempests, and at times its waves lash with fury the sands and the rocks along its banks. It was first discovered by Columbus, who sailed across its mouth, but did not venture inland. Toward the fourth decade of the sixteenth century Diego de Ordaz entered the river, and after navigating its course for about twelve hundred miles, deviated into one of its most important tributaries, the River Meta, which he ascended until he found himself not far from the first spurs of the Cordillera which dart into the plains. Here he abandoned his ships and betook himself to the land, climbing the abrupt sides of the mountains, until he arrived at the vast plateau of Bogota, the seat of the empire of the Muiscas and the Chibchas, second only in its power and development among those found in the new world, after the discovery by Columbus, to those of the Aztecs and of the Incas in Mexico and Peru respectively. Here he encountered two other expeditions of Spaniards who had come, the one from the north, from the shores of the Atlantic, and the other from the south, having entered the continent by the Pacific coast, all in quest of gold, searching for that

* Contributed by Senor Don Santiago Perez Triana, who has lately returned from a canoe voyage on the Orinoco, and published in the Journal of the Society of Arts.



OPIUM HARVEST.

famous Eldorado which lured the conquerors of the new world from one region to another and from one zone to a more remote one.

The aspect of the Orinoco, with very slight alterations to be found at places far distant from one another, remains the same as when the daring Spanish adventurers navigated its waters for the first time. Its course runs first from south to north until it encounters a low range of mountains, or rather hills, which deviate the stream into an easterly direction. A struggle of centuries must have taken place at this spot where, along a stretch of about thirty miles, the river is incased within very narrow limits, and rushes madly between the granite walls on either side, and plunging into deep and wide hollows, where the waters froth and bubble, and seem to rest prior to darting again through other and similar straight passages, and so on until they reach the open plains, and follow their course uninterrupted to the sea.

These rapids divide the river into two well defined parts—the Upper and the Lower Orinoco—and have acted as a barrier, which has kept the lands and the rivers beyond it almost unknown to and unexploited by man. One detail is worthy of mention, namely, that the rapids of the Orinoco are not due, as is the case of other great rivers, to a sudden and great descent of level; they are the result of the compression of an immense volume of water into a very narrow channel, studded with mighty rocks, which have withstood the onslaught of the waters, a channel along which the waters rush with extreme violence and rapidity.

The numerous tributaries that form themselves into the lordly current known as the Orinoco flow into it in all directions, from the north, from the south, from the east, and from the west. Most of them are navigable and receive other affluents, which in their turn are navigable also, so that the whole system constitutes a vast and prodigious network of rivers, carried deep into the very heart of the continent, to the foot of the mountains, and into the inmost recesses of the forests and plains. This network is, in truth, a complicated system of natural highways, which, were they placed longitudinally, would attain a length of many thousands and thousands of miles. Besides the running waters of the rivers, there are certain other water channels called caños, which connect some of the rivers with the others in a similar way to that obtained in other countries by means of artificial canals. Among these the caño of the Casi Quiare deserves special mention, as it connects the system of the Orinoco with the Rio Negro, which, in its turn, forms part of the Amazon system, so that those two great inland seas, the Orinoco and the Amazon, are united by these means.

Two well defined seasons divide the year in the vast valley through which the Orinoco tends its course—the wet season, lasting from May to November, and the dry season from November to May. The trade winds blow during the dry season and clear the atmosphere from the miasmas and exhalations of the soil, purifying it and rendering the climate cool and salubrious. Evidently the influence of population would tend to make these regions far more healthy and inhabitable than what they are to-day.

The forests abound in all sorts of natural wealth; precious timbers, medicinal and resinous plants, India rubber, and all the best known and most highly prized of the tropical products are found in exuberant abundance. The plains themselves are covered with natural grass, which affords the best kind of pasture, whereon the flocks thrive and multiply as rapidly as anywhere else on the surface of the globe; but little use is as yet made of all this immense supply of natural wealth. Along the Lower Orinoco there are some large cattle estates studded here and there, at immense distances from each other. On the shores of one of the largest tributaries, the Caura, and those of the Orinoco itself near the Caura, large forests of tonga bean—a species of aromatic almond used for medicinal purposes and for the preparation of perfumes—have been discovered and exploited for quite a number of years. Some few attempts at exploiting the rubber forests have been made with fairly good results, but this may be said to constitute all the work thus far done toward exploiting these regions.

The only city deserving that name which is found on the Orinoco is the old city of Angostura, now Ciudad Bolivar, named thus in memory of the liberator of the northern republics of South America. It was built by the Spaniards on a bluff overshadowing the river, 300 miles from its mouth, at a place where its waters are

LINGAM IDOLS AND PENITENTS.

THE BURNING GHAT ON THE GANGES.

PORTRAIT OF DR. BOECK IN THE DAK BUNGALOW.

encompassed within a very narrow strait, as the word Angostura indicates "narrowness." From this city steamers ply up the stream about every fortnight as far as the river Apure, two or three hundred miles to the west, and then turn into that river and up to the old city of San Fernando; and this is the sum total of the present navigation existing on the Orinoco, with the exception of the ocean steamers that penetrate into the river from the sea, and sail as far as Ciudad Bolivar.

The lonely traveler paddling along slowly in his canoe, or sailing along with the wind, when it is favorable, contemplates the exuberant natural wealth displayed on both shores of the river as they pass before his eyes, admires the magnitude of the numerous affluents that flow into the main stream from either side, and unconsciously forms the conviction that all these vast natural elements must necessarily be destined to form some day the basis of a mighty center of civilization and human industry, toward which end Nature has so lavishly contributed all her gifts, even to the facility of means of transportation, the highroads open to commerce, without which no people can attain greatness or large industrial and commercial development.

Beyond the rapids, that is to say on the Upper Orinoco, the forests are thicker, the affluents more numerous, and the climate healthier. Many tribes of Indians still remain scattered in these boundless regions. They are of a tame and peaceful disposition, and can be brought under the sway of civilization without any great effort or difficulty.

One special source of wealth attracts the eye of the traveler in the Upper Orinoco and its affluents. That is the abundance of rubber forests of identical quality to those which are to be found on the Upper Amazon. At the present day rubber forests are being sought for in all directions, and yet those of the Orinoco seem to be forgotten or ignored.

The republics of Colombia and Venezuela are the owners of the immense regions watered by the Orinoco. Little is known in either of them about this important part of their territory, and certainly no efforts are being made to obtain from it the products which it so abundantly offers. The problem of exploiting these vast regions is not one of difficult solution. A few steamers on the lower river, a few more on the upper and its numerous tributaries, and some sort of railway along the banks to connect the two parts of the river, facilitating the passing of the rapids, is all that is required. It is a work to be undertaken with the protection of the two governments, as from the moment that private individuals can be sure of the means of transportation, they would flock to those regions, where wealth can be obtained with more certainty and less danger than in the gold fields now and anon found in different parts of the world, to which thousands are attracted, and where so many hopes and so many lives are destroyed and lost.

It is to be hoped that this vast region will ere long attract the attention of those able to place it within the reach of modern industry and commerce. Energies that lie latent in the old world, and ambitions that are unsatisfied, would find on the Orinoco and its shores an ample and remunerative field.

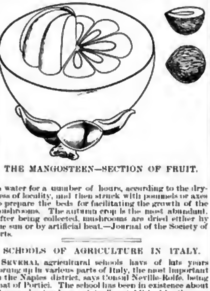
THE MANGOSTEEN.

Thanks to the courtesy of the authorities at Kew, we have been enabled to taste a ripe fruit of the mangosteen, grown in Trinidad, and sent home by Mr. Hart. The fruit is of the size of a small orange, leathery, purple, with a thick green four to five leaved calyx at the base, and a sessile four to five lobed stigma at the top, the stigmatic lobes long, club-shaped, flattened. Each seed is enveloped in a white or pinkish juicy pulp, which has a very delicate and agreeable flavor, though it does not here bear out the eulogistic verdict of travelers. The thick, leathery rind offers ample protection, so that its importation should be easy. In 1875 similar fruits were sent us by Mr. Prestoe, also from Trinidad.—Gardeners' Chronicle.

THE MANGOSTEEN (GARCINIA MANGOSTANA).

JAPANESE MUSHROOMS.

Mr. Robert P. Porter, who has been conducting investigations into the industries of Japan, states that one of the most interesting studies in that country is the growing of mushrooms in the Shikoku Island, where most of the camphor is produced. This is an important article of export, mostly to China, and during the year 1895, the last year for which the returns are available, the quantity of mushrooms exported from Japan to all countries amounted to 1,780,307 lb. Of the numerous species of edible mushrooms, the one called Shiitake is the most important, being abundantly exported abroad and also used for many culinary purposes at home. Logs which are used for cultivating this mushroom are various species of oak. The principal districts where this mushroom is produced are the provinces forming Shikoku, Kiushiu, Wakayama, and Shizuoka prefectures. Oak trees 25 to 33 years old are felled in the autumn, and incisions made with axes at intervals of 3 or 4 inches, the incisions generally reaching the woody layer. The trees are then cut into logs of 4 to 5 feet in length and left in dark secluded parts of the forest. After the third year, mushrooms make their appearance in the incised portions. When the growth lessens they are replaced by new logs. The mushroom grows at each season of the year, winter, spring, summer and autumn, but the growth in winter and spring is the result of artificial stimulus. The logs are steeped



THE MANGOSTEEN—SECTION OF FRUIT.

in water for a number of hours, according to the dryness of locality, and then struck with pommels or axes to prepare the beds for facilitating the growth of the mushrooms. The autumn crop is the most abundant. After being collected, mushrooms are dried either by the sun or by artificial heat.—Journal of the Society of Arts.

SCHOOLS OF AGRICULTURE IN ITALY.

Several agricultural schools have of late years sprung up in various parts of Italy, the most important in the Naples district, says Consul Neville-Rolfe, being that of Portici. The school has been in existence about 24 years, having been originally established by the province, but it was taken over by the state, and re-established by royal charter in 1885. A portion of the disused Royal Palace was given over to its use, the spacious grounds, gardens, and useful group of farm buildings being especially adapted to that purpose. The instruction is conducted by sixteen professors, each of whom takes his own branch of the subject, as chemistry, botany, horticulture, zoology, entomology, geology, farm accounts, meteorology, physics, forestry, irrigation, etc., and lectures upon it. The course occupies three years, after which students who satisfy the examiners obtain the degree of Laureato Agronomo, or bachelor of agriculture. Besides the lectures, practical instruction is given in the field, and the making of cheese, wine and oil is systematically carried on. It is, in short, an agricultural university; 670 scholars have passed through the school, of whom 228 have obtained degrees, and there are 21 freshmen inscribed for the coming year. Most of the laureates become professors in other colleges in Italy, and some have gone to other places, such as Cairo, Buenos Ayres, and San Francisco. One very useful branch of the institution is the exhibition of agricultural machinery, upon which the future of Italian husbandry depends so much, and another the dissemination of pamphlets by the various professors on their special subjects. Of these last there is a very interesting one by Professor Italo Giglioli, the head of the school, on the importation of Italian fruit into Great Britain. He begins by stating that the total importation of fruit into the British Isles has risen from £5,977,351, in 1880, to £7,287,566, in 1890, with a steady annual increase. Besides this, in 1890, nuts to the value of £622,936 were imported. In 1890, only 4 per cent. of the fruit imported into Great Britain came from her own colonies, and 8 per cent. from Italy, but the professor is strongly of opinion that while the colonies have increased their export to a very large extent, the next decennial period will show that Italy has not been idle, and that with more attention to cultivation, packing, and means of transport, the Italian fruit will obtain a more influential place in Great Britain, which is shown to be the most influential fruit market in the world.—Journal of the Society of Arts.

AGRICULTERAL POSSIBILITIES OF THE YUKON VALLEY.

No doubt many on this coast, says the Mining and Scientific Press, San Francisco, Cal., will be interested in a sketch of the agricultural possibilities of the great Alaskan valley, which is now so prominent in the minds of gold seekers. It is from a Minnesota man, and the California reader will of course remember that his standards of comparison are very different from those a Californian would employ. The following is from a correspondent residing in Faribault, Minnesota:

The Alaskan Winter.—The winters in the Yukon valley are not much different from those of northern Minnesota in their influence upon the white man. The cold is more prolonged and severe, but the extreme dryness of the air, in a large measure, offsets this difficulty, and a man who has labored outdoors through a northern Minnesota winter will not notice much difference in the cold of the two localities in its effect upon his constitution. On the Yukon there are frequent periods during the winter when a man must desist from all outdoor work, and the thermometer drops down to 70° below zero, but I have on several occasions seen the mercury go as low as 60° below zero in Minnesota. From this, it appears that the cold is not to be regarded as so great an obstacle of that region as it has usually been.

Area and Soils.—The Yukon valley is so vast in extent that it is difficult to realize its size, and a very large portion of it is identical with the Red River valley of Minnesota in formation and in soil. The upper terraces of that portion of the Yukon valley which lies below the point where the river makes its exit from the mountains are immense level tracts of deep, rich soil which are only slightly broken at long intervals. So level, indeed, are these flats that the eye can seldom detect any change in the surface on them, and a furrow twenty-five miles long might be turned in many places without a break. The Pacific Ocean exerts a profound influence on the climate of the valley, and the changes of the seasons are wonderfully abrupt and decisive. When the spring comes, the sudden disappearance of the ice and snow, and the bursting forth of green verdure, are all but magical. The quick growth of plant life, and the perfection it attains, are truly remarkable. But it seems to be fully accounted for when the conditions of soil and climate that exist in the valley are understood. During the summer the ground never entirely thaws out. The surface is quickly released from the frost to the depth of 4 to 10 feet, according to location and character of the soil, and this frozen state of the subsoil is the principal factor in the growth of plant life. The summer is one long day of three months' duration. The sun swings round in a circle and is above the horizon from twenty-one to twenty-four hours each day, so that, for this lengthy period, it never becomes dark, and the ground has no chance to chill; no frost falls, and the thermometer ranges from 90° upward in the sun during these three months.

Moisture and Crops.—Again, the dryness of the air renders this prolonged, excessive heat as easy for man to withstand as a 75° to 95° temperature in Minnesota. It is seldom that rain falls during this short but potent summer, and storms of wind and hail are unknown. But the more prolonged the drought and heat may be, the quicker and more perfect is the growth of all plant life present, and the wide valley is clothed in deepest green during these summer months. The secret of this is that an abundant supply of moisture is furnished by the frozen subsoil, that slowly thaws and steadily releases the water stored in it, which is brought to the surface through the channels of capillary evaporation. This moisture is but slightly above the freezing point when it is absorbed by the roots of the growing plants, and it must exert a highly beneficial influence by counteracting the fierce heat that steadily assails the surface of the ground. Under these peculiar conditions of the natural forces of nature it is easily realized that a number of our staple crops will succeed and reach perfection in the Yukon valley. Scotch Fife wheat produces enormous yields of the very highest grade of that grain, which has been proved, by test, to make the best class of patent fancy flour. Barley and oats, potatoes and roots of all sorts and many of the garden vegetables, also reach surprising perfection. In the case of barley grown in the Yukon valley, the malt makers would likely find the very highest grade of grain for their use, which might soon take precedence throughout the world. The growing barley would not be subject to the vicissitudes it is in the States, and especially it would escape the injury from rains during harvest, and when standing in the shock, which lowers the quality of this grain more than any other.

Present State of Farming.—There are already a number of small farms in the valley which have been opened by disappointed gold seekers, and it is from the results secured on these that I have drawn my most trustworthy information. These farmers are reaping a rich harvest of dollars. The miners stand ready to pay high prices for vegetables, and even for grains, which they grind into coarse meal for bread. This is the golden side of the picture of prospective farm life in that semipolar region.

The Drawbacks.—But there is a darker side to life in that far northern country, which will likely appear to those used to the comforts of farm houses in the States as insurmountable. The long, cold winter, with its constant night of nearly three months, when the landscape is wrapped in deep gloom, and when only a faint flicker of twilight and the changing play of the aurora borealis shining on the white snow reflect a faint, uncertain light, is likely to give a dubious aspect to the Yukon country. This dismal and dangerous period of the year, coupled with the incredible swarms of mosquitoes and flies in the summer, which make it impossible for horses or cattle to exist, seems to outweigh the favorable features of the valley. Mules and

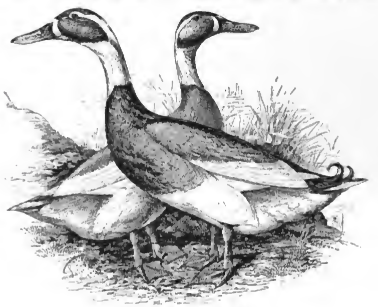
the reindeer will be the beasts of burden in that country if it be ever brought under cultivation. Sheep and hogs will, no doubt, be easily acclimated, and goats may take the place of the cow. The reindeer is a very valuable animal. It makes an excellent beast of burden, furnishes good meat, is easily reared, and is in its native home in that climate, and will take the place of the horse and the ox.

Anticipations.—If, however, a railroad should be built to connect the great Yukon valley with the commercial world, and wheat growing prove to be a profitable business there, the work would likely be done mostly by steam. There is plenty of coal in all districts of the valley, which will furnish cheap fuel for every purpose. On those great flats a traction engine can run a gang plow, turning furrows miles in length, and fields of 50,000 or more acres of wheat would likely be a common sight. The people could live in villages for mutual protection, and in the spring, summer and fall carry forward their farm work on the largest scale. Here the bonanza farm would find its true sphere, with room for all who wished to enter that class of business, and the great Yukon valley could be made to supply the marts of the world with the very highest grade of wheat that would, no doubt, command a better price than that of any other country. Neither are we to presume that this is a painting of the fancy. It will likely become a reality at no distant date.

INDIAN RUNNER DUCKS.

A VARIETY of duck has within the last few years attained a measure of popularity, known as the Indian runner; but has been bred for a long period—some claim for more than fifty years—in Cumberland and North Lancashire. It is a small bird, but the flesh is very good, and it is an abundant layer of medium sized eggs, having the further virtue of commencing to lay long before other ducks begin operations, which is an important consideration.

The evidence as to the origin of this duck is not very clear, but it appears to have come from India. Mr. J. Donald, who has done much to popularize the runner duck, says on this point: "A drake and trio of ducks were originally brought from India by a sea captain to Whitehaven, and presented to some friends, who at that time followed the occupation of farming in West Cumberland. Their extraordinary laying properties, producing a supply of eggs long before ordinary ducks commenced to lay, and continuing long after they had ceased, was sufficient to very strongly impress the economic mind of the Cumberland farmer, and for long they were exclusively in this one man's hands; but after their fame as layers extended, the drakes were eagerly sought after, and largely employed to cross the ordinary farmyard ducks of the country, with a view to improving their egg-producing qualities. Another consignment was imported by the same gentleman some years later, and from these two importations it is probable that all the present day runner ducks are either directly or indirectly descended. They were not known to their introducer by any special or distinctive name, having simply attracted his attention when ashore by their active habits and peculiar penguin carriage."



INDIAN RUNNER DUCKS.

These birds are very active, excellent foragers, and specially useful in keeping down slugs and worms in gardens, obtaining a great portion of their food in this manner. They are, as already stated, remarkably good layers, which quality, combined with great vigor, is their chief claim to popular favor. The flesh is small in quantity, but excellent in flavor, and they do not fatten at all well. They are, as a rule, non-sitters, and when broody, which is seldom, are by no means reliable.

Quoting again from Mr. Donald, the following is that gentleman's description of the breed: Both drake and duck should be close and tightly feathered, with very erect carriage. Compared with other domestic ducks they are small, their average weight being from 3½ pounds to 4½ pounds each. They are alert and sprightly, with very active habits, nearly always being on the move. The head is fine and comparatively flat, with the eyes high up. The bill is very strong, at the base broad and long, coming straight down from the skull, giving it a wedge-shaped appearance. The neck is long and very fine, a character which is seen in its greatest perfection during the spring months, more especially in ducks when in full lay. The body is long and narrow, elevated in front, and the head carried high, giving a peculiar erect carriage when on the move; but the carriage is not so much of the penguin form now as formerly, and whether this effect is owing to climatic influences, the introduction of foreign blood into many strains, or to in-breeding, it is difficult to say with accuracy, but probably they have all shared to a greater or less degree in producing this effect.

The head of the duck is a faint grayish fawn and that of the drake a bronzy green, with a narrow band of white running round the base of the bill at its junction with the head in both duck and drake. The bill of the duck is a dull cucumber shade, while the drake has more of a yellowish green. The colored parts of the body of both drake and duck are of a soft fawn shade, that of the drake being finely pencilled, and giving it a somewhat deeper reddish brown tinge toward the upper part of the breast, while the feathers of the duck have a brownish center to each feather, and a fine lacing of a lighter buff shade at the margin. The upper part of the tail and curl feathers of the drake is of a darker shade, somewhat resembling the color of his head. The legs in both duck and drake are orange red.

Hitherto the Indian runner has not been much used for crossing, but at the Royal Agricultural Show at Manchester, in June last, the first prize in cross breds were Aylesbury and runner cross, and they were splendid in quality, very fleshy, and only a few ounces in weight below the Aylesbury and Pekin cross. From this it would appear that the cross is better than we expected, and it is one which deserves further attention. —Edward Brown, F.L.S. We are indebted to the Gardeners' Magazine for t e cut and copy.

THE KLONDIKE PLACERS.*

WHEN the attention of the world was called to the new Canadian gold fields during the past summer, few people had ever heard of the Yukon placers. Nevertheless, prospecting has been carried on for over fifteen years throughout the whole length of the river, both in the northwestern territory of Canada and across the border in Alaska. The number of gold diggers at work tended to increase from year to year, but the severity of the climate and the difficulty of getting supplies into the country checked its progress, especially before 1892, when the first steamers were placed on the river by a trading company. In 1896 the total production of gold amounted to little more than £100,000, with about two thousand miners at work, and although some of this was produced on the Canadian side of the boundary, little attention was paid to it by the Geological Survey of the Dominion, and it was reported as if it were a part of the Alaska output.

On September 6, 1896, however, Mr W. Ogilvie, the surveyor of the Yukon district, reported to the Canadian government that rich discoveries of gold had been made on Bonanza Creek, a tributary of the Klondike, which flows into the Yukon some fifty miles southeast of Fort Cudahy, where he was stationed, and about the same distance from the United States boundary. Mr. Ogilvie continued to make reports during the winter, and, from his book on the subject, lately published by the Dominion government, most of the following information is obtained. The discovery was made by G. W. Cormack, who had been in the country since 1887, and a rush from Cudahy at once took place, two hundred claims extending twenty miles along the creek being staked out within a fortnight of the time when the strike became known. Later on, when the neighboring creeks El Dorado, Hunker, Dry Fork and West Fork were found to promise well, the other diggings on the Yukon were almost entirely deserted. Miners traveled with sleds over the snow from Circle City and other places still farther off in United States territory, and by January, 1897, two thousand men were encamped on and around the Klondike, with scanty supplies and little protection against the cold, although a temperature of 50° below zero Fahrenheit was not unusual. Many men bought a share in the claims even as early as this for thousands of dollars, and the few laborers who preferred to work for hire received one and one-half dollars per hour, working as long as they liked.

Little gold was actually recovered in the winter, the "pay dirt" being dug out and piled up to wait until the spring, when the frost had gone and water was plentiful. Some extraordinary yields were announced, however, as the result of prospecting washings, two hundred and fifty dollars in a pan (containing about one-quarter of a cubic foot of gravel) being reported, but not generally believed. There is little doubt, however, that from one to ten dollars per pan was usually recovered in El Dorado and Bonanza Creeks, although the diggers, as is their wont, were very reticent.

In spite of this reticence and the lack of communication with the outside world, news of important discoveries leaked out, and in the early spring the rush into the Yukon basin from British Columbia and California was unprecedented. By May over two thousand people had entered the country by one route or another, and were pushing on to the Klondike, where the town lots of Dawson City had been staked out, and building was in progress. At the beginning of July the population of Dawson City had risen to five thousand, and more people kept coming in; but the supplies brought by them were far from being adequate, so that the scarcity of provisions continued almost unabated, and as the summer wore on became more and more pronounced, until it was evident that the seven thousand people who will be shut up there in the ensuing winter must suffer serious privations, if not absolute starvation, before the Yukon River becomes navigable again next spring.

Meanwhile, about July 15, the first miners from Klondike reached San Francisco, bringing with them about £400,000 in gold, and the excitement, which had been growing on the Pacific seaboard, became intense, and spread over the whole of the United States and Canada, and even reached England. Thousands of people started for the Yukon without sufficient supplies, and regardless of the fact that it was already too late in the season. Fortunately, the means of transport failed. The steamers on the Yukon were delayed, owing to the lowness of the water in the river; and the difficulty of transporting large quantities of stores over the passes leading from the seaboard to the interior prevented the southern route from being used by the majority of the emigrants, so that not one in ten of those who started late in the summer succeeded in reaching the Klondike, and starvation, if it comes, will not be largely due to the newspaper boom of July and August.

Turning from the history of the district to the description of the gold fields themselves, it may be remarked at once that the placers, which have caused so much excitement, do not present any very unusual features. The gravels are in general about 20 ft. thick, and, as usual, the parts immediately overlying the bed rock are the richest. The pay dirt is, however, said to be frequently 5 or 6 ft. thick, and about 30 ft. wide, the whole width of the creek beds varying from 100 ft. to 600 ft. or more. The gold is very coarse, and is, therefore, easy to save with crude washing appliances. It is of lower standard than most placer gold, containing only about 800 per 1,000 of gold, while the average fineness of Californian gold is about 880 and of Australian about 950. No very large nuggets have been found yet, the largest recorded being worth about £3 10s., and in this particular the placers resemble those of the Pacific coast generally, where large nuggets are very scarce.

Mr. Ogilvie considers that the auriferous gravels have been derived from the crystalline ro[illegible] lying to the south of the Klondike, between it and [illegible] River, which also contains gold, but no [illegible] been brought forward as to their age. A[illegible] point in connection with the question of age is that the ground remains perennially frozen, on[illegible] being thawed in summer to the depth of [illegible] feet. It would appear, therefore, that, like the placers of Siberia, these deposits have remained undisturbed and unaltered ever since the glacial period, and perhaps some such evidence of this will, in course of time, be discovered as was afforded by the remains of mammoths and other animals in the Siberian frozen mud.

It is worthy of note that the comparative lowness of standard of the gold is, under the existing conditions, in favor of the view that the placer gold is derived from the erosion of auriferous quartz lodes formerly existing at a higher level, and has not been formed in situ by being deposited from solution. For, according to those who support the former view, placer gold becomes of higher standard than reef gold after it has found its way into the drifts, the base metals being gradually removed by the solvent action of running water, in which gold is not readily soluble. Since, however, the Klondike gold has been frozen up during a large part of the time since it was deposited in the gravel, it is obvious that it cannot have altered in composition so much as the gold in river sands further south, and might be expected to resemble the gold in the parent lodes, which is not usually more than 800 fine. The low standard of the gold is not so readily accounted for by the accretion theory of formation of placer gold. Some auriferous veins have already been discovered both in the creek valleys and on the mountains round them, although no direct evidence has yet been adduced to connect these lodes with the sources of the placer gold. Moreover, many nuggets have been found adhering to quartz, so that the weight of evidence appears to be in favor of the view that the gold in these placers, at any rate, has been laid down there by mechanical rather than chemical processes.

The method of working the placers resembles that followed in the frozen placers in the transbaikal in eastern Siberia. Prospecting is done chiefly in the short summer when the snows are gone and water is plentiful, but the excavation of the gravel is best carried on in winter, when nothing else can be done. The shafts are sunk to the pay dirt, and tunnels are then run through the gravel, following the rich material wherever it may be. To soften the ground a pile of wood is placed against the end of the drift and set on fire, the gravel, to the depth of about one foot, being brought down by pick and shovel after the fire has gone out. As M. Levat points out in speaking of the Siberian placers (Engineering and Mining Journal,

* From Nature.

June 12, 1897, the method is not an ideal one, but the circumstances are difficult. The frozen soil cannot be easily worked with the pick, as it does not break, but simply mats together under a blow. For the same reason powder and dynamite have little effect; moreover, the drilling of the alluvium through which quartz bowlders are scattered is a slow and costly work. The gravel is piled up to await the arrival of spring, when it is washed in the cradle or in short sluices, which are expensive, owing to the high cost of timber.

The future of the country can hardly be foreseen as yet. It is certain that next year hundreds of miles of unworked creek beds will be vigorously prospected by the thousands who will enter and find that all the ground on the tributaries of the Klondike is already occupied. If, as seems likely, other fairly rich placers are found, many of the men will remain in the country, and with the development of the auriferous quartz lodes and the beds of lignite, some of which have already been discovered, the Yukon district of Canada will probably become one of the steady producers of gold like California or Colorado. The output this year will probably not greatly exceed £800,000, partly owing to the scarcity of water in the creeks last summer, which interfered with the washing in the creeks. Nevertheless, the Canadian production of gold for 1897 will, with this addition, be raised to over £1,000,000, or considerably above that of 1893, which amounted to £900,000, and is still the highest on record. There is little doubt that this will be largely augmented in the next few years, and that the Yukon district will be the richest Canadian gold field yet discovered.

T. K. ROSE.

PALESTINE EXPLORATION.*

THE object of exploration is to obtain accurate knowledge of a country, its inhabitants and its extant monuments and texts. That of Palestine has special interest to Christian races and to Jews, as serving to explain more clearly the sacred literature of their faith.

The results of such exploration may be judged by looking back a century to the time of Bayle, Voltaire and Astruc, when what was regarded as advanced scientific work assumed that the Hebrews were a savage race without literature, that history only began to be written about 500 B. C., and that the oldest civilization was that of China and India. It is now known that the art of writing was practiced in Egypt and Chaldea as early as 3000 B. C., that the Canaanites, about the time of Joshua, had a civilization equal to that of surrounding nations, as had also the Hebrew kings; while, on the other hand, Chinese civilization is only traceable to about 800 B. C., and that of India was derived from the later Persians, Arabs and Greeks. These results are due solely to exploration.

The requirements for exploration demand a knowledge, not only of Syrian antiquities, but of those of neighboring nations. It is necessary to understand the scripts and languages in use, and to study the original records as well as the art and architecture of various ages and countries. Much of our information is derived from Egyptian and Assyrian records of conquest, as well as from the monuments of Palestine itself. As regards scripts, the earliest alphabetic texts date only from about 900 B. C., but previous to this period we have to deal with the cuneiform, the Egyptian, the Hittite and the Cypriote characters.

The explorer must know the history of the cuneiform from 2700 B. C. down to the Greek and Roman age, and the changes which occurred in the forms of some 550 characters originally hieroglyphics, but finally reduced to a rude alphabet by the Persians, and used not only in Babylonia and Assyria, but also as early as 1500 B. C. in Asia Minor, Syria, Armenia, Palestine and even by special scribes in Egypt. He should also be able to read the various Egyptian scripts—the 400 hieroglyphics of the monuments, the hieratic, or running hand of the papyri, and the later demotic. The Hittite characters are quite distinct, and number at least 130 characters, used in Syria and Asia Minor from 1500 B. C., or earlier, down to about 700 B. C. The study of these characters is in its infancy. The syllabary of Cyprus was a character derived from these Hittite hieroglyphics, and used by the Greeks about 300 B. C. It includes some fifty characters, and was probably the original system whence the Phoenician alphabet was derived. As regards alphabets, the explorer must study the early Phoenician and the Hebrew, Samaritan and Moabite, with the later Aramean branch of this alphabet, whence square Hebrew is derived. He must also know the Ionian alphabet, whence Greek and Roman characters arose, and the early Arab scripts—Palmyrene, Nabathean and Sabean, whence are derived the Syriac, Cufic, Arabic and Himyaritic alphabets.

As regards languages, the scholars of the last century had to deal only with Hebrew, Aramaic, Syriac, Coptic and Greek, but as the result of exploration we now deal with the Ancient Egyptian whence Coptic is derived, and with various languages in cuneiform script, including the Akkadian (resembling pure Turkish) and the allied dialects of Susa, Media, Armenia and of the Hittites; the Assyrian, the earliest and most elaborate of Semitic languages; and Aryan tongues, such as the Persian, the Vannic and the Lycian.

The art and architecture of Western Asia also furnish much information as to religious ideas, customs, dress and history, including inscribed seals and amulets, early coins and gems. The explorer must also study the remains of Greek, Roman, Arab and Crusader periods, in order to distinguish these from the earlier remains of the Canaanites, Phoenicians, Hebrews, Egyptians and Assyrians, as well as the art of the Jews and Gnostics about the Christian era, and the later pagan structures down to the fourth century A. D.

The monuments actually found in Palestine are few, though important. The discovery at Tell el Amarna of about 150 letters written by Phoenicians, Philistines and Amorites—and in one case by a Hittite prince—to the kings of Egypt proves, however, the use of cuneiform on clay tablets by the Syrians as early as 1500 B. C., and one such letter has been recovered in the ruins of Lachish. The oldest monuments referring to Syria and Palestine are found at Tell Loh, on the Lower Euphrates, and date from 2700 B. C. Next to these are the Karnak lists of Thothmes III, about 1600 B. C., recording the names of 119 towns in Palestine, conquered after the defeat of the Hittites at Megiddo. These lists show that the town names which occur in the Bible are mainly Canaanite, and were not of Hebrew origin. The Canaanite language of this period was practically the same as the Assyrian, excepting that of the Hittites, which was akin to the Akkadian.

In the next century the Tell el Amarna tablets show that the Canaanites had walled cities, temples, chariots and a fully developed native art. They record the defeat of the Egyptians in the north by Hittites and Amorites, and the invasion of the south by the Abiri, in whom Drs. Zimmern and Winckler recognize the Hebrews, the period coinciding with the Old Testament date for Joshua's conquest.

An inscription of Mineptah, discovered in 1896, speaks of the Israelites as already inhabiting Palestine about 1200 B. C., and agrees with the preceding. Other Egyptian records refer to the conquests of Rameses II in Galilee and in Syria, when the Hittites retained their independence; and in the time of Rehoboam, Shishak has left a list of his conquests of 133 towns in Palestine, including the names of many towns noticed in the Bible.

The Hittite texts found at Hamath, Carchemish and Merash, as well as in Asia Minor, belonged to temples and accompany sculptures of religious origin. They are still imperfectly understood, but the character of the languages, the Mongol origin of the people, and the equality of their civilization to that of their neighbors, have been established, while their history is recovered from Egyptian and Assyrian notices. The Amorites were a Semitic people akin to the Assyrians, and their language and civilization are known from their own records, while they are represented at Karnak with Semitic features.

The oldest alphabetic text is that of the Moabite stone about 900 B. C., found at Dibon, east of the Dead Sea, on a pillar of basalt, and recording the victories of King Mesha over the Hebrews, as mentioned in the Bible. Several Bible towns are noticed, with the name of King Omri, and the language, through approaching Hebrew very closely, gives us a Moabite dialect akin to the Syrian, which is preserved in texts at Samalia, in the extreme north of Syria, dating from 800 B. C. The Phoenician inscriptions found at Jaffa, Acre, Tyre, Sidon, Gebal and in Cyprus, do not date earlier than 600 B. C., and show us a distinct dialect less like Hebrew than the Moabite. The most important of these early texts is the Siloam inscription in the rock-cut aqueduct above the pool, found by a Jewish boy in 1880. It refers only to the cutting of the aqueduct (in the time of Hezekiah), but it gives us the alphabet of the Hebrews and a language the same as that of Isaiah's contemporary writings. It is the only true Hebrew record yet found on monuments, and confirms the Old Testament account of Hezekiah's work.

The Assyrian records refer to the capture of Damascus by Tiglath Pileser III, in 732 B. C., and of Samaria in 722 B. C., as well as to Sennacherib's attack on Jerusalem in 702 B. C. The latter record witnesses also the civilization of the Hebrews under Hezekiah, whose name occurs as well as those of Jehu, Azariah, Menahem, Ahaz, Pekah and Hosea, who, with Manasseh, gave tribute to Assyrian kings.

About the Christian era Greek texts occur in Palestine, the most important being that of Herod's Temple, at Jerusalem, forbidding strangers to enter, and those of Siah, in Bashan, where also Herod erected a temple to a pagan deity. Such texts are very numerous in Decapolis, where a Greek population appears to have settled in the time of Christ.

The geographical results of exploration are also important for critical purposes. Out of about 500 towns in Palestine noticed in the Old Testament, 400 retain their ancient names, and about 150 of these were unknown before the survey of the country in 1872-82. The result of these discoveries has been to show that the topography of the Bible is accurate, and that the writers must have had an intimate knowledge of the land.

Among the most interesting Old Testament sites may be mentioned Lachish, Debir, Megiddo, Mahanaim, Gezer and Adullam as newly identified; and of New Testament sites, Bethabara, Ænon and Sychar, all noticed in the fourth Gospel.

The existing Hebrew remains are few as compared with Roman, Arab and Norman ruins of later ages. They include tombs, aqueducts and fortress walls, with seals, weights and coins. The most important are the walls of the outer court of Herod's great temple at Jerusalem, with his palace at Herodium, and buildings at Cæsarea and Samaria. The curious semi-Greek palace of Hyrcanus, at Tyrus, in Gilead, dates from 176 B. C. In upper Galilee and east of Jordan there are many rude stone monuments—dolmens and standing stones—probably of Canaanite origin, as are the small bronze and pottery idols found in the ruins of Lachish. Sculptured bass-reliefs are, however, not found in Palestine proper, having been probably destroyed by the Hebrews.

This slight sketch may suffice to show the advance in knowledge due to exploration during the last thirty years. The result has been a great change in educated opinion as to the antiquity of civilization among the Hebrews and Jews, and as to the historic reliability of the Bible records. Further exploration, especially by excavation, may be expected to produce yet more interesting results, and deserves general support, as all classes of thinkers agree in the desirability of increasing actual knowledge of the past. It is no longer possible to regard the Hebrews as an ignorant and savage people, or to consider their sacred writings as belonging necessarily to the later times of subjection under the Persians. Internal criticism is checked and controlled by the results of exploration, and by the recovery of independent historical notices.

We are indebted to Nature for the above particulars.

* A discourse at the Royal Institution by Lieut.-Col. C. R. Conder.

German statistics for 1896 show that there died within the empire, immediately killed by boiler explosions, or within 48 hours of the accident, 30 persons, 2 were badly injured, and 13 slightly hurt. The causes were, in 8 cases insufficient water supply, brought about in 3 of these 8 cases by careless supervision, in 1 case inadequate material, in 2 cases local wear, and 1 case each was due to bad reparation, old fissures, worn material, over pressure, sediment of mud and calcium sulphate.—Uhland's Wochenschrift.

SELECTED FORMULÆ.

Decolorizing or Bleaching Linseed Oil.—Bleached linseed oil may be prepared by everybody without much cost or trouble, says the Neue Deutsche Maler Zeitung, since only a little of it is required at best. If it is to be done by the aid of chemical bodies, the process of oxidizing or bleaching is best performed by means of peroxide of hydrogen, a clear liquid of siruplike consistency. For this purpose, the linseed oil to be bleached is mixed with 5 per cent. peroxide of hydrogen in a tin or glass bottle, and the mixture is shaken well repeatedly. After a few days have elapsed the linseed oil is entirely bleached and clarified, so that it can be poured off from the peroxide of hydrogen, which has been reduced to oxide of hydrogen, i. e., water, by the process of oxidation. The use of another oxidizing medium, such as chloride of lime and hydrochloric acid or bichromate of calcium and sulphuric acid, etc., cannot be recommended to the layman, as the operation requires more care and is not without danger. If there is no hurry about the preparation of bleached linseed oil, sun bleaching seems to be the most recommendable method. For this only a glass bottle is required, or, better still, a flat glass dish, of any shape, which can be covered with a protruding piece of glass. For the admission of air, lay some sticks of wood over the dish and the glass on top. The thinner the layer of linseed oil, the quicker will be the oxidation process. It is, of course, necessary to place the vessel in such a manner that it is exposed to the rays of the sun for many hours daily.

Carbon Paper.—Melt 10 parts lard, 1 part of wax, and mix with a sufficient quantity of fine lampblack. Saturate unglazed paper with this, remove excess and press.

Coloring Gun Barrels.—Bluing Barrels.—The bluing of gun barrels is effected by heating evenly in a muffle until the desired blue color is raised, the barrel being first made clean and bright with emery cloth, leaving no marks of grease or dirt upon the metal when the bluing takes place, and then allow to cool in the air. It requires considerable experience to obtain an even clear blue. Browning Guns.—The following recipe for browning is from the United States Ordnance Manual: Spirits of wine, 1½ ounce; tincture of iron, 1½ ounce; corrosive sublimate, 1½ ounce; sweet spirits of niter, 1½ ounce; blue vitriol, 1 ounce; nitric acid, ¾ ounce. Mix and dissolve in 1 quart of warm water and keep in a glass jar. Clean the barrel well with caustic soda water to remove grease or oil. Then clean the surface of all stains and marks by emery paper or cloth, so as to produce an even, bright surface for the acid to act upon, and one without finger marks. Stop the bore and vent with wooden plugs. Then apply the mixture to every part with a sponge or rag, and expose to the air for twenty-four hours, when the loose rust should be rubbed off with a steel scratch brush. Use the mixture and the scratch brush twice, and more if necessary, and finally wash in boiling water, dry quickly, and wipe with linseed oil or varnish with shellac.

Enamel for Copper Cooking Vessels.—To enamel copper cooking vessels, white fluorspar is ground to a fine powder and strongly calcined with an equal volume of unburnt gypsum, at a light glowing heat, stirring diligently. Then grind the mixture to a paste with water, paint the vessel with it, using a brush, or pour in the paste like a glaze and dry the same. Increase the heat gradually and bring the vessels with the glass substance quickly into strong heat, under a suitable covering or a mantle of burnt clay. The substance soon forms a white, opaque enamel, which adheres firmly to the copper. It can stand pretty hard knocks without cracking, is adapted for cooking purposes and not attacked by acid matters. If the glassy substance is desired to cling well and firmly to the copper, a sudden and severe heat must be observed.

Hektograph Sheets.—Soak 4 parts of best white glue in a mixture of 5 parts of water and 3 parts of solution of ammonia, until the glue is soft. Warm the mixture until the glue is dissolved and add 3 parts of granulated sugar and 8 parts of glycerine, stirring well and letting come to the boiling point. While hot, paint it upon white blotting paper with a broad copying brush, until the paper is thoroughly soaked and a thin coating remains on the surface. Allow it to dry for two or three days and it is then ready for use. An aniline ink should be used for writing, and before transferring to the blotting paper, wet the latter with a damped sponge and allow it to stand one or two minutes. Then proceed to make copies in the ordinary way. If the sheets are laid aside for two days, the old writing sinks in and does not require to be washed off.—Chem. and Drug.

Cigar Flavoring.—

(1) Macerate 2 ounces of cinnamon and 4 ounces of tonka beans, ground fine, in 1 quart of rum.

(2) Moisten ordinary cigars with a strong tincture of cascarilla, to which a little gum benzoin and storax may be added. Some persons add a small quantity of camphor, or oil of cloves or cassia.

(3)

Tincture of valerian	4	drachms.
Butyric aldehyde	4	"
Nitrous ether	1	"
Tincture vanilla	2	"
Alcohol	5	ounces.
Water, enough to make	16	"

(4) The following formula was contributed to an exchange some years ago as one which was put up for cigar manufacturers:

Extract vanilla	4	ounces.
Alcohol, Jamaica rum, } of each	½	gallon.
Tincture valerian	8	ounces.
Caraway seed	2	"
English valerian root	2	"
Bitter orange peel	2	"
Tonka beans	4	drachms.
Myrrh	16	ounces.

Soak the myrrh for three days in 6 quarts of water (?), add the alcohol, tincture valerian and extract of vanilla, and after grinding the other ingredients to a coarse powder, put all together in a jug and macerate for two weeks, occasionally shaking; lastly, strain.—Pharmaceutical Era.

ENGINEERING NOTES.

Charles Parsons, the inventor of the steam turbine which was fitted in the 100 foot torpedo boat Turbinia, giving her a speed of 33 knots an hour, is about to construct at Newcastle-on-Tyne a vessel of the torpedo boat destroyer type with turbine engines. It is stated that she will have a speed of 36 to 40 knots an hour.

What is said to be the largest dredge ever built has lately been put together in Buffalo. It is 140 feet long, 40 feet wide, and 12 feet deep. The fifteen ton clam-shell bucket will operate at a depth of 80 feet, forcing up 10 cubic yards of mud at once. The dredge is named Fin McCool (Finn MacCumhail), who, according to legend, was the strongest Irishman in the world.

For years the St. Gothard tunnel has been famous as the longest in the world, extending nearly nine and a half miles. The glory of this tunnel is about to depart, as the longest tunnel is about to be constructed in England. It is to be on the line of the London and Northwestern Railway Company, which has decided to bore through the steep incline known as Shapfall, with which travelers to Scotland are more or less familiar.

H and W. Pataky, of Berlin, have constructed a simple apparatus for arriving at a comparative idea of the value of a packing or lagging material. It is simply a gas pipe connected with a steam pipe, with valve and manometer. The pipe is provided with a discharge cock at its lower end. The pipe is coated with the material in question, and steam is admitted into it, the cock first being left open. After a while the cock is closed, the pipe is filled with steam, but the valve is not closed. The steam continues to circulate and to condense. The condensed water will finally reach a mark made on a water gage. From the period which has elapsed, the heat conductivity of the material can be estimated.

From some experiments on the pneumatic caissons of the new quays at Bordeaux, M. A. Pasqueau is of the opinion that it is possible for men to work under compressed air at a pressure of about 77 lb. per square inch, which is equivalent to about 170 ft. sea water, but for this depth the pressure should not be reduced at a quicker rate than 10 minutes to about 1½ lb. He also recommends that the chamber in which work is being done should be warmed to from 68 to 86 deg. Fahr.; that the air lock should be supplied with fresh air during the time the pressure is being let down; that no valves controlling air should be manipulated by the workmen; and that in order to lessen fatigue the men should be brought to the surface by mechanical lifts.

A mass of copper and silver ore weighing 3,567 pounds, from the great Anaconda copper mine of Butte, Mont., has been presented by H. B. Parsons, vice-president of the Anaconda Copper Mining Company, to the Museum of the Brooklyn Institute of Arts and Sciences. The big chunk of ore was carted from the office of Wells, Fargo & Company, 63 Broadway, recently, to Brooklyn, a crowd gathering in the street while it was being removed from the express office. The mass contains, per assay, 75·04 per cent. of pure copper and pure silver at the ratio of 50·05 ounces to the ton. The metal in it is worth $375. It is the second largest mass of Anaconda ore ever brought east, one piece weighing 5,000 pounds having been sent to the Chicago World's Fair. Its donor, Mr. Parsons, is a trustee of the Brooklyn Institute.

A New York-Chicago limited train, consisting of seven cars, has just been turned out of the shops of the Wagner Palace Car Company, and will shortly be put in operation by the New York Central & Hudson River Railroad, says Engineering News. The train will make the trip between Chicago and New York in twenty-four hours, and will be known as the New Lake Shore Limited. It consists of a buffet smoking car, a dining car, a drawing room car, three sleeping cars and a compartment observation car. The cars are connected by wide vestibules, and have Pintsch gas ceiling lights and electric berth lights, the electric lighting system adopted being the Gibbs. The baggage room of the buffet smoking car contains the 30 horse power Westinghouse engine and dynamo for electric lighting. The train is luxuriously equipped throughout, having bath, barber shop, library, waiting room, stenographers' and typewriters' service, the latter being free, besides the usual conveniences and comforts of the regular Wagner car service. Perhaps the most distinctive features of the train as a whole are the provisions made for persons or parties designing to travel as privately as possible, there being private state rooms, private dining rooms, etc., with separate wash rooms and toilet conveniences. In the interior the cars exhibit a variety of styles of decoration, but on the outside all are alike, being the regular Wagner palace car color, sparingly decorated with gold leaf.

A plan is being perfected by the navy department for the establishment of a complete system of signal stations along the Atlantic coast, by which ships of the navy passing near the shore may receive messages from and send them to Washington authorities. Such a system has been in operation abroad, and has performed valuable service for the navy. It is intended to use, when practicable, the life saving stations for signal towers, and where such stations are not well located new ones are to be established for the exclusive use of the signal service. A board has been appointed by Secretary Long to report a practicable measure. This board consists of Commander Schoeder, Lieut. Gibbons, Lieut. Harlow, and Lieut. Anderson of the New York Naval Militia, and has been in session several days. Along the Long Island shore, and at other points where the life saving service cannot be utilized for the new scheme, stations will be placed in charge of members of the State militia, which will have entire charge of the system in time of war. Communication from one station to another will be had by telephone and telegraph, so that it will be possible for the movements of a fleet sailing well inshore to be kept in touch with the entire system. It is probable that the government will have a special line of wire to Washington, in order that it may be kept in prompt communication with the signal stations when necessary. For years Great Britain, France, and other European powers have used a like system extensively, and with a chain of life saving stations extending from Maine to Florida it will not be difficult for the navy to apply it here.

ELECTRICAL NOTES.

It has been suggested to use a new unit of length for very great distances, such as those in astronomy, over which an electrical impulse could be sent in one second; it is assumed that in one second a current impulse would travel seven times around the earth. According to this it is stated by an Austrian contemporary, says The Electrical World, that a message could be sent to the moon in one second, while it would take eight minutes to reach the sun. The nearest star would receive a message after four years. There are fixed stars which are still visible which to-day would not have received the news of the discovery of America, while there are still others at which the news of the birth of Christ would not have been received.

In 1869 there were sent in Belgium 1,722,586 commercial telegrams and 315,722 telegrams relating to the service of the telegraph, which required no toll. The receipts amounted to 1,322,000 francs. The Hughes printing telegraph instrument was then adopted, and, with some improvements, is still used. Ten years later multiple telegraphy was adopted upon commercial lines and has since grown so that upon all wires this rapid system is used more or less. A report made at the close of the year 1894 shows for Belgium alone 34,740 kilometers of wire, including the telephone service of 23,236 kilometers. Private line wires in 1895 were 58,078 kilometers. Upon these lines of telegraph there were used 1,806 instruments, employing 8,739 people.

It has long been held from practical experience that the network of wires now found in many towns protects those places from the effects of lightning, and probably also prevents many thunderstorms from breaking over them. An official inquiry has been recently made in Germany as to the influence exerted by telephone wires on atmospheric electricity, with a view to set at rest the question whether danger from lightning stroke is increased or diminished by a close network of wires. The inquiry has shown that the wires tend to weaken the violence and diminish the danger of lightning stroke. Returns obtained from three hundred and forty towns provided, and from five hundred and sixty not provided with a telephone system, show that the danger varies in the proportion of 1 to 4·6 between the two cases.—Invention.

A table taken from the annual reports of the Railroad Commissioners of New York and Massachusetts for nearly all of the street railway properties shows the cost of the electric power required to run a car one mile under average conditions of load, etc. The table gives, says The Street Railway Journal, the number of cars owned, the car mileage per year and the cost of the electric power per mile and per passenger. Of the nineteen companies operating less than two hundred and fifty thousand car miles, four are obtaining power at a cost of less than 2 cents per car, six between 2 and 3 cents, five between 3 and 4 cents, one between 4 and 5 cents, and three at more than 5 cents; of the five companies operating over five million car miles per year, one obtains the power at less than 1 cent per car mile, three between 1 and 2 cents, and one between 2 and 3 cents; other similar figures are also given between these limits. The Brooklyn Heights Company has the cheapest power, 0·86 per car mile, followed by the Binghamton, with 0·94; the cost of power for Massachusetts roads includes repairs and depreciation of the station plant, which is not the case of the New York roads.

The chief idea underlying the proposal which Bochet has made to the Société Internationale des Electriciens is not strikingly novel, and all will depend upon the details of his device. We remember several patents concerning contacts exposed at the height of the cars for long conductor strips fixed on one side of the top of the cars in such a way that the conductor is always in contact with one of the terminals. Le Génie Civil, which reports upon Bochet's paper, illustrates one of his proposals, which fixes the contacts to short brackets attached to the lamp posts. Two cars are shown joined in order to get a greater length for the conductor above. That will not always be possible, and to place poles at distances of less than the length of an ordinary train car apart does not look very hopeful either. There must be considerable difficulties in carrying out projects of such apparent simplicity. Otherwise the trolley would have had to go, for the objections to the trolley remain strong. In some parts of Berlin, where the buzzing aerial conductors were not to be tolerated, short conduit sections have been tried during the last months. But all sorts of things, as we see from a paper by Fischer-Dick, in Glaser's Annalen, children's iron hoops among them, got into the slot, and the contact plows showed the severe wear very distinctly.

A very clever mail delivery box has been placed in a number of the larger buildings at Geneva, Switzerland, by an enterprising electrician, says The Electrical Engineer. This mail box has a compartment for each of the stories of the building, and when the letters are deposited on the ground floor the carrier delivers them as required. The deposit of a single letter makes an electric contact, which starts a bell going on the respective floor, which does not cease ringing until the letter is taken out. At the same time it opens the faucet of a tank on the roof of the house, which causes water to flow into the cylinder forming the counterweight of the mail box elevator until the weight is heavier than the box, when the box ascends and the flow of water ceases simultaneously. As the box passes each story, the mail intended for it—letters, papers and small packages—falls into boxes in the corridor on that floor. This is performed very reliably by a little spring at the bottom of each compartment in the elevator mail box, which causes the bottom of the compartment to catch for a moment, and the release throws out even a single piece of paper thinner than a postal card into the stationary box provided for its reception. When the box has passed the uppermost floor, the cylinder filled with water strikes a bolt provided at the bottom, which allows the water to flow out, and by its own weight the box descends to its place on the ground floor. Should by any mischance a single piece of paper have remained in the elevator, upon striking the bottom it will at once go through the same series of movements as before.

MISCELLANEOUS NOTES.

Over 140,000 persons traveled through Switzerland in government post chaises and diligences last year. Of these 77,736 went into the Engadine by the Schyn Julier, Albula, Fluela, and Bernina passes; 14,616 were transported over the Ober Alp; 14,173 over the Splugen; 8,676 over the Bernardin; and 7,502 over the Simplon.

A publication has been issued by William T. Lewis, president of the Philadelphia Horological Society, on the lubrication of watches, chronometers and clocks. In these few pages he emphasizes the fact, among others, that even the best made watch cannot keep accurate time from year to year unless lubricated with the finest quality of oil. Among the sources of lubricants for this purpose mention is made of porpoise jaw oil and blackfish "melon" oil as having become widely and justly celebrated in all parts of the world for lubricating fine and delicate machinery. The blackfish melon oil derives its name from the mass from which it is extracted, taken from the top of the head of the blackfish, reaching from the spout hole to the end of the nose and from the top of the head down to the upper jaw.

According to a recent paper by Mr. Corbet Woodall, the cost of carbureted water gas in England is determined chiefly by the price at which oil can be bought. The sources of supply are the wells of Russia and America, and also, though to a small extent only, the shale oil works of Scotland. At present suitable oil can be purchased at 5 cents per gallon at English ports, which represents about 5·5 cents at the average gas works. Gas of an illuminating value of 20 candles will require 3 gallons of oil per 1,000 cubic feet, and 40 pounds of coke will also be used in making that quantity. The cost of making gas of 20 candle power, with oil at 5·5 cents per gallon and coke at $3.00 per ton, will be 32 cents per 1,000 feet in the gasholders. This is about the same as the current average cost of making coal gas of 15 candles.

In a recent lecture by Prof. A. H. Sabin in Brooklyn, N. Y., on the corrosion of iron and steel, the fact was noted of iron lying in the ground 1,000 years and being dug up in a fairly well preserved condition; while, on the other hand, modern water pipes which have been underground only a few years have been found badly rust eaten, and in Boston recently a thick cast iron water pipe was taken up and sections of it had corrosive holes from the size of a walnut to that of an apple. Still further, this contrast between the former and later periods is seen in the fact that even in structures exposed but to the action of the air, the steel has been seen to decay in a comparatively short time, and steel beams have had to be frequently removed from buildings. Once the work of corrosion sets in, the progress of chemical decline is quick.

Cheap houses for workmen are being built in Leipsic by "The Society for Building Cheap Houses for Workmen." This society has already built 30 houses, valued at $387,216, and providing 361 lodgings for families and 38 for single persons. As the society only demands 3 per cent. returns on its capital, it rents houses on the following terms: Single rooms, $9.50 to $14.25 per annum; apartments of three rooms, from $31 to $38, and of four rooms, $36 to $47. A small garden costs 4 cents per week additional, and for 5 cents per day a child will be cared for, including its meals. Rent is payable weekly, and the deficit caused by delayed payments amounts to only 6 per cent. on the total receipts. No tenant is allowed to sublet rooms, and the proprietor must give a week's notice and the rentor three months' notice before changing.

We do not know that the town of Ludwigshafen, situated opposite Mannheim on the Rhine, has particularly suffered from fires, but we see that they have ordered a skeleton house with three rows of windows for fire brigade practice, and also for drying the fire hose. The iron structure consists of a ground floor in corrugated iron, and three stories of open angle iron work, rising to a height of 48 feet, and further overtopped by an iron pipe, 27 inches wide, extending to a height of 71 feet. This iron pipe, in which the hose is to be dried, does not reach down to the ground. The whole structure is to be fixed to any foundation, and can easily be taken to pieces and transported. Ludwigshafen is quite a modern industrial town. In 1840 not 100 souls were living on the spot; at present the many and varied works give employment to almost 40,000 people. The structure, which has three windows in each row, front and back, and two in each on the sides, is being built by W. Martin, of Marten, Westphalia. The order is somewhat unusual for a small town.

According to one writer of the modern school, the best way to dispose of broken china is a method that is not quite new, but one that is being revived. The result is almost pretty enough to console a housewife for the loss of her cherished china. This means of disposition requires a large number of broken pieces, the more and the smaller they are the better. The only accessories needed in the process of saving broken china are plentiful supplies of putty, a smooth surface like a board or a flower jar, and a bottle of gilding. There are two methods of procedure. One is to cover the board or jar with putty and pat it down smooth and even before beginning to stick on the broken pieces. This method is preferable if one has enough pieces to finish the whole surface at one sitting. If not, it is better to take a small lump of putty for each piece, fitting it down and putting the next one into place beside it, and so on until the surface is covered. The putty which oozes up between the pieces is then gilded, and the process, so far as the broken pieces are concerned, is over. So far, only the bare material for articles of use has been manufactured, but there is no end to the list of uses to which it may be put. Some women use it for picture frames, others for imitation tiling or mosaic. If one has a large supply of broken dishes, an ugly mantelshelf can be greatly beautified in this manner. It would require the savings of several families for this, however, and unless the mantel is very small, it is rather too ambitious an undertaking for a beginner. It may be mentioned that if putty is used for the purpose above indicated, it might be an improvement to adulterate it largely with white lead, as used by our grandmothers, and a still greater improvement might be to use plaster of Paris tempered with whiting.

GRAIN ELEVATOR IN COPENHAGEN.

The imposing grain elevators and stores that have recently been erected in European seaports prove that the greatest attention is given, not only in the United States but also in Europe, to arrangements and apparatus relating to the storing of grain and to this branch of commerce, and as we think it may be of interest to some of our readers to see just how a building devoted to such purposes is arranged, we publish herewith engravings giving the elevation and cross section of the grain elevator of the Kjöbenhavns Frihavns Aktieselskab in Copenhagen. It stands on the end of a pier 187 ft. wide; the quays on each side are about 43 ft. wide and each of them is provided with railroad tracks that are connected at the ends by turn tables and cross tracks.

A tunnel runs along the quay which is designed for the reception of pipes, electric cables, etc., and into this tunnel six cross tunnels open on each side, which contain twelve carrier belts that can be loaded from

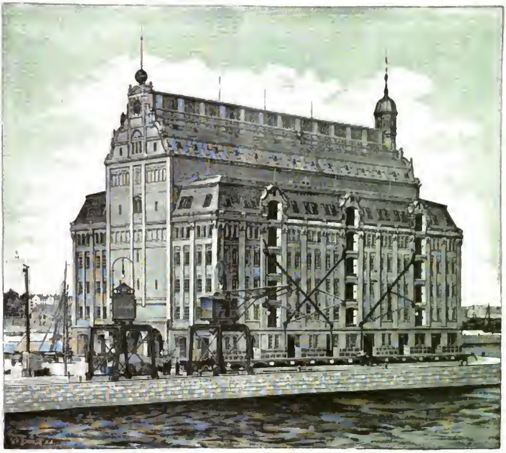


Fig. 1.—GRAIN STOREHOUSE AND ELEVATOR IN COPENHAGEN.

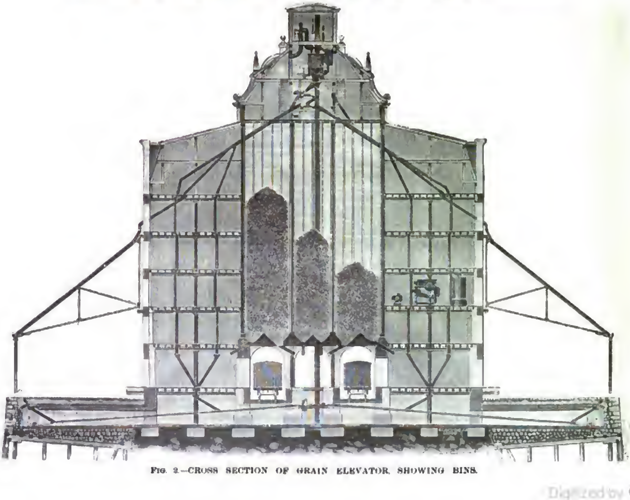

Fig. 2.—CROSS SECTION OF GRAIN ELEVATOR, SHOWING BINS.

openings in the main tunnel when the iron covering is removed.

The building is 170 ft. 7 in. long, 108 ft. 4 in. broad, 42 ft. 7 in. of which breadth is taken up by the bins, and 128 ft. high from the cellar floor to the roof. The bins, thirty-six in number, have a height of 65 ft. 7 in., a length of 15 ft. and a breadth of 12 ft. 5 in., and each one holds two hundred tons. The funnel-shaped floors are made of beton laid between I beams and rest on wrought iron pillars. At each center there is a pressure of 900,000 lb. The walls of the bins are made of boards secured to standards, only the outer walls of the two groups, each of which consists of eighteen bins, being fireproof. The rooms of the different stories, or lofts, are provided with double floors with a filling of sheets of asbestos on wooden beams, iron beams and pillars.

The elevators designed for unloading the grain from vessels have not yet been built, and so for the present it is raised by means of the hoisting devices of the vessel, which throw it into tubes that conduct it to the carrier belts. These belts consist of impregnated hemp, are 23½ in. wide, and with a speed of 6 ft. 6 in. can carry sixty to seventy tons per hour. As shown in Fig. 2, two belts work on one elevator, but only one at a time, of course, one being always cut out. The grain carried in by the belts is raised by elevators 131 ft. long, which have a velocity of 28 ft. and are capable of raising sixty to seventy tons per hour. They are provided with patent buckets 8½ in. wide and 4½ in. high. The lower part of the elevator is provided with tension devices; the upper part is made of iron, and the shafts of the elevator drums and the gearing rest on iron bearings. The wheels have a proportion of 1:4, so that the gearing makes 160 revolutions to 40 of the elevator shafts. The teeth of the wheels are cut. The further transmission to the electric motors is accomplished by means of belts. The space devoted to the machinery is fireproof and elegantly finished.

From the elevators the grain passes on two box scales, each of which weighs one ton at a time. One man takes charge of two scales. While one is being filled the other is tared and emptied by means of a lever on the box; then, by means of a second lever, the supply is admitted to the other box and this one is tared. Sixty boxes are weighed per hour; that is, one per minute. In order to avoid the terrible dust which arises when some kinds of grain are weighed, the scale holders are uncovered and air is sucked through the small opening, whereby the escape of the dust is prevented.

The weighed grain falls into a revoluble funnel or hopper, which conducts it to the next story or bin, or, if it is to be stored at a greater distance from the scales, it is conducted to the proper belt, which carries it to the desired place. Each belt has two deflectors which direct the grain to the right or left in the tubes or to the belt again. These deflectors are moved mechanically by chains, the movement of which is regulated by a pull on the guide rope. By means of this arrangement and the conducting tubes on the different stories the work is carried on; the grain is unloaded from the vessels, weighed, and stored in the desired bin or floor of the building. A similar arrangement serves for circulating the grain and loading the vessels.

If the grain is to be loaded on a vessel, the adjustable loading tubes are set in operation, and these, with the vertical hanging tubes, deliver the grain directly to the hold of the vessel. If this is to be reversed, the next tube is opened by turning a funnel-shaped head. At first the grain runs by its own weight through the tubes on the particular carrier belt and elevator, but later it is necessary to shovel it. When it is discharged from the elevator, it is subjected to a current of air which blows off the fine dust and chaff; then it passes through the adjustable funnels and the proper tubes, back to the desired floor. It is evident that the effect obtained by this ventilation is quite different from that obtained by the old hand turning on the different floors.

A cleaning machine is provided for the thorough cleaning and separation of the coarser parts.

All of these machines are driven by electricity from the central harbor station, which furnishes 100 horse power, driving five primary dynamos at 450 volts. The distribution of the electric energy is accomplished by means of the triple conductor system at 2 × 250 volts. In the bins there are six electric motors of 15 horse power, for operating the elevators, one for the upper carrier belts and the exhauster, two in the cellar for operating the belts there, and one for the cleaning machine; ten in all. There are also two electric hoisting devices with two direct coupled 20 horse power motors. These raise one ton 1 ft. 7 in. per second.

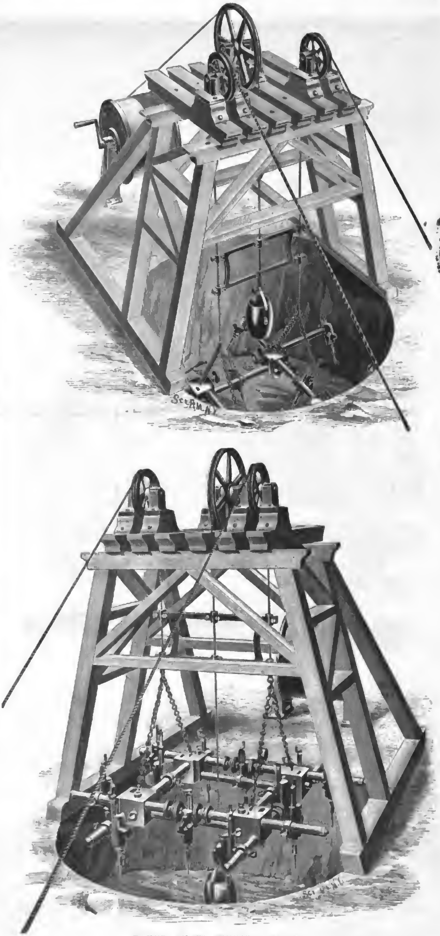
The electric driving devices, which are here used on a larger scale than ever before, have proved excellent. The fact that they are always ready for use and that they do away with the heavy transmission bands or ropes which are usually carried to the upper stories render this superior to all other methods.—Oesterreichische Monatsschrift für den Oeffentlichen Baudienst.

McCULLOCH'S FRAME [illegible]ING ROUND SHAFTS.

THE sinking of a roun[illegible] present known appliances, is a far mor[illegible]ration than the sinking of a rectangular [illegible] rectangular shaft, varying from 7 ft. to 8 f[illegible]ar of that length, fixed to the sides of th[illegible] retain its rigidity sufficiently when the [illegible] operation; but in a round shaft, where a f[illegible] to be the whole span of the shaft's diamete[illegible] too great to secure the rigidity of the ba[illegible]rills are in operation; hence tripods and [illegible] have to be used, which are ineffective [illegible]rk, and entail a maximum amount of lab[illegible] with a minimum result in the speed of [illegible]Culloch's shaft-sinking frame is so design[illegible] bars on which the drills are operated sha[illegible] rigid, removing at once all difficulties c[illegible]h the sinking of round shafts, and enab[illegible] be sunk with an economy in working and [illegible] in sinking never yet attained.

Seeing, then [illegible]orking on mounted bars or tripods canno[illegible]ective duty as they would if fixed on perf[illegible] bars, it necessarily follows that to attain a maximum speed in sinking: (1) The drills, to give their full duty, should work on a perfectly rigid bar or bars, and that these bars should be arranged so as to get as large a number of drills as possible working in the shaft simultaneously. (2) That they should be placed and adjusted on the bars so as to pitch the blasting holes in the shaft in the most advantageous positions, in order that the maximum result may be obtained when blasting. (3) That after the boring of the floor of the shaft is completed, the whole of the frame and boring plant shall be removed expeditiously and easily out of reach of the blasting.

The inventor claims that he has secured all these essential advantages in this sinking frame. (1) The drills, when in the act of boring, will give out their full effective duty, as the bars on which they are fixed

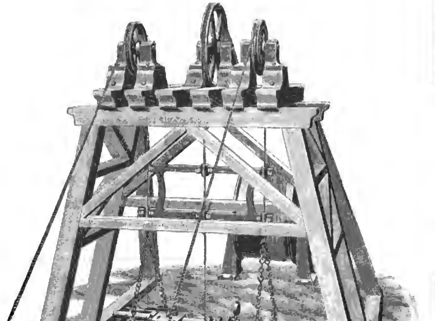


ROUND SHAFT SINKING FRAME.

remain perfectly rigid against the circumference of the shaft, and the frame is designed to carry twelve or any less number of drills, of which all or any number desired can be worked simultaneously. (2) The drills can be so placed and adjusted on the bars that they will command any part of the shaft, and with ease. (3) And lastly, the whole of the frame, with the drills still fixed on the bars and other tackle, can be hoisted in one operation out of the reach of the blasting, and it is so arranged that the hauling to surface of the broken rock passes through the center of the frame; it is, therefore, not necessary to hoist the frame to the surface, but only so far as will remove it out of reach of damage in blasting.

The inventor also claims other advantages in the use of this sinking frame. It will serve as a template or guide in the sinking of a shaft. It can be utilized as a scaffold for the bricking up of a shaft. It can be used as well for the examination or fixing of the pump or gear work of a shaft.

The frame is suspended from a poppet head with hoisting gear both for the frame and kibble. It is lowered by two ropes working from the poppet head of the shaft, and is attached to the crossheads of the frame, and these ropes pass through a guide. The kibble rope also passes through the same guide, thus preventing the kibble from swaying, and avoiding as well any possible entanglement with the frame ropes.



ROUND SHAFT SINKING FRAME.

The frame is built up of hollow steel tubes—twelve in all—on which twelve or any less number of clamps are placed. The center of the frame is a square of four fixed bars, held together by four strong crossheads. The movable bars—eight in number—pass through these crossheads, at right angles to the fixed bars or framing, and are moved quickly to the circumference of the shaft by a rack and pinion. The cone parts of each bar are then screwed up against the shaft by a screw operated at the back end of the bars, and which moves within the bars or tubes. The importance of this arrangement is very great. It enables the frame to be tightened up against the shaft when the drills are in actual operation, and not in any way altering their position, or the holes that are being bored. It is also automatic in its movement, for whenever the frame is loosened—through the jar and vibration of the drills, or from any other cause—the lever and weight attached to each screw of the bar has a tendency to tighten the frame against the shaft's circumference. The movable bars are all held tightly and firmly in position by set screws and pads. The frame has only to be lowered to the required distance from the floor of the shaft, tightened against the circumference, and it is at once ready for work.

This frame is shown by the Tuckingmill Foundry Company, at the exhibition of the Royal Cornwall Polytechnic Society, Falmouth and Camborne. We are indebted to The London Engineer for the cuts and particulars.

CHINA AND HER RAILWAYS.

ONE of the greatest paradoxes ever presented to the world in connection with the material advancement of a nation is afforded by China. Boasting of a civilization of remote antiquity, claiming to have invented the mariner's compass, gunpowder, and the art of printing, and priding herself upon the initiation of numerous other attributes of modern civilization, she persistently lags behind in all things most essential to national progress. This is particularly noticeable as regards railways. With the motheaten mantle of a long past age descending upon the shoulders of her rulers, generation after generation, they still hold the doctrine that China is the hereditary fountain of all knowledge and advancement, and that any suggestions coming from the West must be, in the nature of things, either retrogressive or only prompted by sinister motives. When by force of circumstances, and owing to external influences, China has been persuaded into taking a step in advance, she has afterward repented of her wisdom, and has willfully demolished in a day the fabric that cost her years to rear. This was the attitude she assumed twenty years since with regard to the Shanghai-Woosung Railway, which was the first line ever constructed in China. It was regarded as a barbarian innovation, and no sooner had the ten miles of railway been built, equipped, started and begun to pay, than the whole line was dismantled and torn up, its stations and other buildings razed to the ground, and some of the constructive materials thrown into the river. It was opened in 1876 and wrecked in the following year. Curiously enough, the Chinese have a proverb that "true wisdom lies not in servile imitation of the past, but in availing one's self of such improvement as experience may have suggested." Pregnant words, full of wisdom to Chinamen in theory, but worse than a dead letter to them in practice.

The reason of this condition of things is not far to seek. It commences with the early education of Chinese officials, and finishes with their effete and corrupt administration when in office. Their utter impotency is a natural result of their education, and they are dominated by the mendacious traditions of their office, which traditions are their lawful and recognized heritage. Not only does their education not fit them for the practical work of government, but by its theoretical and purely academic character it absolutely unfits them for it. Not but what the Chinese educational system is a model of completeness, but it lacks practical backbone. In the mere matter of administration it would form a model for western nations, and yet in itself it constitutes the greatest obstacle to progress. Every youth in the empire is at liberty to compete for the honors awarded to scholarship, and by a process of sifting the candidates are reduced to a very few. The most successful of these, subject only to certain conditions of birth, are eventually installed in the highest government posts. Thus it may be said that the principle of competitive examination is carried to its logical issue, the community being governed by its most learned members. But, unfortunately, the educational system deals only with the lore of the past, modern thought is not only neglected, but regarded with reprobation and contempt. Western ideas, where they differ from those of Confucius, are only regarded as the eccentricities of barbarians. With rulers imbued with notions such as these, it is not to be wondered at that China has never evinced a genuine desire to identify herself with other nations in the cause of material progress.

So far we have indulged more or less in generalities. Let us now enter a little into detail respecting commercial enterprise in China in the past, and so justify our animadversions. For our present purpose three illustrations will suffice, namely, the introduction into China of cotton mills, the electric light and railways. Some twenty years ago a native company was formed for the purpose of establishing a cotton factory in Shanghai. Want of funds retarded the erection of the mills, and after about six years the matter was taken up by another company, partly native and partly foreign, but under the auspices of an American mercantile firm. Steps were quickly taken to have the representative of the American firm secretly arrested upon a trumped up charge and deported to Nankin. The conspiracy, however, was so transparent that the American consul refused to countersign the warrant, and so the matter fell through. The action of the officials, however it may have been prompted, in attempting thus to strangle a foreign innovation, is deserving of the severest reprobation. Nor were the proceedings as regards the introduction of the electric light less worthy of condemnation. A company commenced operations in Shanghai some twelve years since, and the natives readily introduced the new light into various theaters and public saloons within the radius of the concession. No sooner was the enterprise fairly started than the local authorities forbade the use of the electric light by all Chinese, and at the same time the foreign consuls were requested to order the municipal council to remove all the electric lamps in the public streets on account of their mysterious and dangerous nature. The consuls had little trouble in giving a suitable reply to the latter request, but the natives in the foreign settlement, who are, of course, civilly and criminally responsible to their own authorities, had no alternative but to submit.

The opposition to the introduction of railways into China, more especially trunk lines, has proceeded not so much from any aversion to the innovation on the part of the people as to the fact that the officials throughout the empire recognize the danger thereby threatened to the system of illegal taxation on which they thrive. This fact has not been sufficiently realized by the advocates of the introduction of this system of locomotion. Let us briefly trace the history of this advocacy and its results. It is now about forty years since steamboats were successfully introduced into Chinese waters. Some ten years later the late Sir R. Macdonald Stephenson, who had already done so much for the development of railways in India, visited China on a similar mission. The people enthusiastically welcomed him, and his advocacy apparently broke down the last flimsy thread of native prejudice. But Sir R. Macdonald had to reckon with other than the people before he could lay his foundations for the enterprise. The local rulers were up in arms, and raised a general opposition to railways, fearing, as we have pointed out, that they would interfere with their privileges in turning their local taxing powers to the best account. A contributor to this result was probably the very completeness of the scheme which Sir R. Macdonald placed before the authorities. Had he confined himself to a short trial line, he might have been successful in driving in the thin end of the wedge. But fresh from his Indian victories, his scheme embraced the bringing of Calcutta into railway communication with Peking. Hence his motives were either misunderstood or only regarded with suspicion, and so railways in China were not yet to be.

But the idea was not given up. Hope springs eternal in the English contractor's breast, and so it came to pass that, after a time, it occurred to those interested in the matter that the construction of a short line at one of the ports amenable to European influence might form the basis of some extended operations subsequently. Hence the Shanghai-Woosung Railway, the history of which enterprise is not without interest nor its fate without a lesson. In 1865 a company was formed for constructing a line on this route, by which means the changeable and difficult navigation of the river between those two points would be superseded. At the bottom of this scheme were Messrs. Jardine Matheson & Company, who were ever consistent supporters of the various efforts to introduce railways into China. They came to the conclusion that the only feasible plan was to acquire the land and construct the line themselves. The acquisition was a tedious, difficult and costly process, but it was eventually accomplished and a survey of the line was made by Prof. Henry Robinson, C.E., who was appointed engineer of the line. But Messrs. Matheson were not the only persons who had cast longing eyes on China as a field for railway operations. Independently of that firm, and in entire ignorance of their proceedings, the late Mr. Richard C. Rapier, of the firm of Ransomes & Rapier, of Ipswich, had given his attention to the problem, and he conceived that the best way of making a start toward its solution was to send a short length of line—rails, engines and carriages—to the Emperor of China as a present upon the occasion of his majority and marriage. He thought that if the Emperor once experienced the pleasures of a short railway trip, he would certainly desire an extension of his ride. In 1873 the idea began to take definite shape, the late Duke of Sutherland being the first to associate himself with the project. The King of the Belgians subsequently took an active interest in the scheme, and the writer was with Mr. Rapier in Brussels when the project was placed before his Majesty. The movement was at first well supported in diplomatic circles both in this country and in Belgium, but as this course of procedure was ultimately found to be impolitic, the idea was abandoned.

Mr. Rapier, however, still nursed his long-cherished idea, and did not despair of introducing the railway

system into China. He therefore built a small engine weighing only 22 cwt., and Mr. John Dixon, the well-known contractor, who interested himself in the matter, provided about half a mile of light rails and fastenings, ready to be sent to China with the engine, should opportunity arise. In the meantime, Messrs. Matheson's line was being made, and a coalition of all parties interested was brought about. The idea, then, was to send out the rails and engine, and, so far, equip the Matheson line. But its construction had not been completed, and, what was worse, the allotted funds were nearly exhausted. The railway company had only £30,000 left, which was insufficient to carry out the line. At this juncture Mr. Dixon threw himself into the breach, and liberally undertook to complete the line for £20,000—the balance of the company's capital—and £8,000 in shares. He faithfully carried out his contract; the line was made and equipped, and was opened amid public rejoicings on July 1, 1876. But at one o'clock on October 20, 1877, the last train was run from either end, the line being directly afterward ruthlessly dismantled, having been purchased by the Chinese authorities for that purpose. Portions of the rolling stock and plant were sent to Formosa, the remainder being thrown into the Yang-tse.

Such was the fate of the first railway in China. In recent years, however, owing to native influence, the effort to introduce this system of transport into the country has proved more successful. Witness the Shanhaikwan-Tien-Tsin line with its extension to Peking; and if all goes well, far greater extensions will be witnessed, and railways will yet encircle the Celestial Empire. The Chinese are not wholly a nation of imbeciles. There are men of thought, of astuteness and of business ability among them. Of such is Shêng Ta-jên, whose antecedents, however, judged by European standards, are probably less immaculate than those of most Chinese mandarins. No matter, he has satisfied the Emperor of his intelligence, and climbed into power on the shoulders of Li Hung Chang. He was appointed director-general of railways about a year ago, and he quickly succeeded in obtaining an imperial edict for incorporating the Shanhaikwan Railway, with his proposed great trunk line from Peking to Hankow, which will be about 900 miles in length, and which presents some engineering difficulties. This is a big order even for Shêng Ta-jên, who controls the Chinese telegraph system and the great iron works at Han-Yang, besides which he is a director of the China Merchants' Company and the founder of the new Imperial Bank of China. At the same time it was reported some three months since that a Belgian syndicate had successfully negotiated a contract with the Chinese government for the construction of the Hankow line.

In the meantime Shêng wisely purposes commencing with schemes of lesser magnitude, such as lines connecting Woosung, Shanghai, Hangchau, Soochau and Chingkiang. This route lies through a wealthy and populous district, and presents no constructive difficulties, the total length being about 200 miles. The Shanghai-Woosung line was the first to be tackled, and is in course of construction. It practically follows the route of its ill fated predecessor, and is to be laid on the English 4 ft. 8½ in. gage, which gage has been adopted for all the imperial Chinese lines. It is a purely native undertaking, and the rails are to be supplied by the government iron and steel works at Han-Yang, while the carriages are being built at the government works at Tien Tsin. The sleepers are to be supplied from America, Messrs. S. C. Farnham & Company having secured the contract. The locomotives will be built in the same country by the American Trading Company, the present contract being for three tank engines. The iron bridges have been ordered from Germany and the switches from Belgium. England, the pioneer of railways in China, supplies nothing. Such is the irony of fate. There is, however, a chance yet, provided our labor troubles cease and trade gets reorganized in time. A fair start having thus been made under favorable auspices, it is not inconceivable that a very considerable railway system will eventually be developed in China.—Perry F. Nursey in Industries and Iron.

ANCIENT CLOCK BELLS.

In the representations of the clocks of the end of the fifteenth and of the whole of the sixteenth century we find peculiar arrangements of external bells. We shall explain these, because they are now unknown, the original clocks having disappeared or become disfigured.

In the clocks of those times the hammers were very large and were mounted upon long levers provided with a tail or prolongation from which frequently depended a wire. It would seem as if this pulling arrangement were a reminiscence of belfry clocks, in which the watchman had to supply the blows that the wheelwork frequently failed to strike; but the case is not the same, and we cannot very well conceive of the owner of a clock striking the incomplete hour himself. In the various representations of the clocks which we have studied we shall find an explanation of these functions.

The owner of a clock, having a bell within reach of his hand, must necessarily have conceived the idea of using it to call up his servants. All that was to be done was to find a hammer arrangement and the proper length of wire. It was, upon the whole, an intimate application of the striking work of belfry clocks, the tolling of the bell of which served formerly, as it does still, to give alarms. We find an example of this call bell in an engraving of a book by Crispin de Passe, entitled Parabole des Vierges, in the National Library of Paris (Fig. 5). This engraving represents a clock upon the top of which there is placed, crosswise, a hammer that is entirely independent of the clock and that must have served for striking the bell. The two functions of call bell and time bell united in the same clock are very clearly shown in an engraving of the sixteenth century found in the Livre des Bons Engins preserved in the National Library (Fig. 4). In fact, we here see, on one side, the isolated hammer with its lever, and, on the other, the hammer that is directly actuated by the wheelwork of the striking train. There is, therefore, no doubt as to what each of them was designed for.

An engraving by Jean Cousin, entitled Fortune, Amour, Temps (Fig. 1), shows us, in a clock held by a female symbolizing Fortune, a bell surmounted by a single hammer with a lever from the extremity of which hangs a wire. This clock has the weights and counterpoises of the movement and striking train, and this conclusively shows that it must have struck the hours in running concurrently with the call bell, or in silence. At the extremity of the wire, in fact, there is a ring which it sufficed to connect with a detent placed in the interior of the movement (as in the clock shown in Fig. 3) in order to have the clock strike the hours, while, when the wire was detached, the clock became silent.

The object, therefore, was to obtain silence when it was deemed advisable; and to effect this was worth while, since, as we have already remarked, these striking arrangements were very powerful, both by the size of the bell and that of the hammer. It must, therefore, have been the desire of the owner of such clocks not to be compelled, under any circumstances, to listen to their often exaggerated noise. There are, moreover, in our own day, clocks that run in silence.

As soon as the striking train of clocks was devised, there was very naturally an effort made to render it interesting, and so its motive power was soon utilized for actuating chimes concurrently with the simple time bell. Therefore, by the side of the ringer of chimes, who from all times had played with more or less talent, the clock repeated the airs of its cylinder automatically. The chimes of belfry clocks and those of house clocks date from the middle ages. The clocks of these remote epochs have nearly all disappeared. The wheel work, worn out by long service, has been suppressed or replaced, and the simple airs of olden times have been changed. One of these airs, dating from the fifteenth century, and which has come down to us, is that of Vendome, which comprised words that were modified according to the locality. The most celebrated chimes were those of Flanders.

There were belfry clock chimes that possessed a decorative character, in the sense that they were sounded by "jacks of the clock" that struck the bells in turn. Such was the clock of Liege. Others were distinguished by the splendor of their wheelwork (Fig. 2); but, in reality, the chimes derived their effects exclusively from the variety and purity of tone of their bells.

Although house clocks also had chimes as long ago as the fifteenth century, it was especially in the sixteenth that they came more and more into use. The bells were so placed in the campaniles as to be visible, or else were concealed in the interior of the frame.

In our collection there is a wooden clock of the end of the sixteenth century which, for its chimes, has six perfectly tuned glass bells, which are fixed in a wooden frame at the top (Fig. 6).

The Louis XIV and Louis XV clocks, which were suspended from the wall, had chimes which were placed either in the case or in the support. In the time of Louis XVI mantel clocks also were provided with them.

In addition to chimes, there were other musical arrangements. Everyone is acquainted with the music produced by the steel comb, which has not changed since the eighteenth century, and everyone has seen music boxes. But dulcimers are not so well known. These are string instruments, like pianos, and the keys of which are actuated by cylinders provided with pins. They have scarcely been applied except in large center-pieces for rooms. The organ stops of clocks and the harmoniflutes have the same system of bellows and pipes as the large church organs and recall the primitive portable organs of the middle ages.

In finishing this brief notice of the curious arrangements introduced into the striking works of clocks, we must not forget the ancient cock and the eternal cuckoo, which, after flapping their wings and opening their bills, sing as many times as there are hours to be indicated. They made their appearance in the middle ages and have been manufactured ever since.

There is still another time-announcing device to be mentioned, and, although it marks the last step in the progress made in this direction, it is not the best. We refer to the phonograph. As for us, we prefer the merry chimes of the days of yore to the voice that announces the hour after the manner of the undertaker's assistant when he calls out that the funeral procession is waiting.—La Nature.

ELECTRIC RAILWAY DEVELOPMENT AT HOME AND ABROAD.

English contractors (Dick, Kerr & Company, of London) have secured the order for the electrical equipment of the street railway systems of Madrid and Barcelona, Spain, but the subcontract for the generators and full station equipment has been placed with the General Electric Company, of Schenectady. The Railway World, of London, states that 100 motor equipments will be required for these lines and that the full amount of the original contract is about $800,000. The following extract from a press dispatch from Schenectady, dated September 26, is an interesting comment on the use of American electrical machinery:

"While Lord Kelvin was in the act of gratifying his intense curiosity about the General Electric works here, news came of the closing in New York of further contracts, employing English capital, for large electric railway systems in Dublin, Madrid and Barcelona. The amount involved is said to reach £300,000. Lord Kelvin was asked his views on this matter. He said: 'I do not consider it out of the way or surprising that these orders should be placed here. England has not yet developed her electric railway work to as large an extent as you have, and hence is buying, as she always does, in the best market to save money. She has the engineering and manufacturing talent, but lacks the opportunity. Here you have towns of 10,000 population springing up in a year, and they naturally want the latest and best, making a good demand, which renders easy production on a large scale and also stimulates the older communities near them. We have no

such developments in England, and the areas of our towns are smaller, so that the necessity of city transportation is not so keenly felt as with you.'"

The same state of affairs was recently considered by The Electrical Engineer, of London, and the remarks of that journal are interesting as showing the British point of view: "We have been pleased to note that the English contracts for electric tramways are being placed more frequently with English contractors, and that in certain cases the English contractors have obtained important contracts abroad in the face of the direct opposition of agents from America. This condition of affairs is gratifying to the profession, but the fact that the majority of the material used, even by English contractors, is obtained from America is to be deprecated. The reason for this is to a certain extent to be found in the fact that the severe competition in America has reduced the prices; but, on the other hand, it is also the fact that in some departments the English manufacturers are not sufficiently prompt to take up the requirements of the new industry. We were informed, for instance, the other day, by a large contracting firm that the steel poles for the construction of an important electric tramway they were equipping had been ordered from an English firm at prices which compared favorably with those of American goods. The order having been placed, considerable trouble arose from the delay in delivery, and the organization of the line was seriously impeded from this cause. Delays of this kind naturally tend to keep the trade out of the country. Another point we have noticed recently, when inspecting new traction plant, is that the American engine builders have paid particular attention to the design of their engines for traction work; whereas the tendency of the English manufacturers is to supply an engine which has been found suitable for electric lighting purposes. It by no means follows that this engine will be suitable for traction work, because the rapid way in which the load varies and the short duration of the periods of extremely heavy loads strain both the engine and its governing arrangements most severely. If our manufacturers will keep themselves to the fore in matters of detail of this kind, we see no reason why the present procedure of ordering goods from abroad should continue. The boom in electric traction which is now commencing will then benefit the English profession and enable the manufacturers to hold their own in colonial tramway equipment. Not only in English speaking countries, but on the Continent electric tramway schemes are being decided upon every day, more particularly, perhaps, in the mountainous regions and other places where there is a plentiful supply of water."

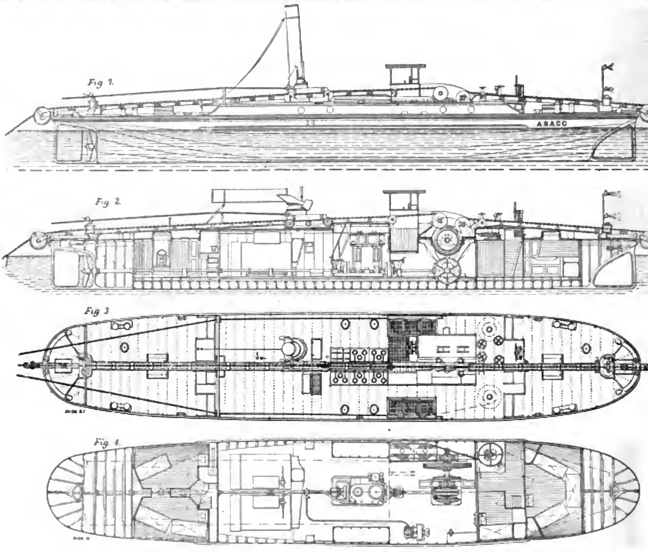
In Australia the American cars are very favorably received, to judge from the following note in Transport: "The railway commissioners of New South Wales are experimenting on the Sydney tram lines with an open car of American make and design. The new car is the theme of local admiration and of eulogistic notices in the press. The old car, which is its companion on the road, is practically deserted. Everybody, in fact, rushes to this elegant and attractive vehicle, which not long ago was publicly tried for the first time. It is said that as a summer car it would be difficult to surpass it. It is perfectly open from end to end, the sun, wind or rain being excluded by cleverly designed blinds, which can be lowered or raised at will, and which, being on the automatic principle, stop just exactly in the position wished. The seats are reversible, being made of light wood, beautifully polished. It runs particularly smoothly, and has accommodation for 40 passengers, with a small cab at each end for the man controlling it. This, of course, is when the car is driven by electricity. The real name is 'The Brill Car,' being manufactured by the firm of that name in Philadelphia. The truck on which it runs is called the 'Peckham' truck. The car being about half the weight of those at present in use, will effect a large saving in haulage."—Western Electrician.

ELECTRIC TOWAGE ON CANALS.

Among the papers read before the spring meeting of the Institution of Mechanical Engineers there was one on "Mechanical Propulsion on Canals," by Mr. L. Robinson. The subject was quite extensively treated in this paper. It was stated that the efficiency of side wheels or a screw applied to towing is half that due to chain haulage. In dead water a chain haulage boat with a force of 100 horse power is equivalent to a tug of 200 horse power; and against a current 100 horse power in the former is equal to 400 in the latter, if the speed of the convoy is equal to that of the current; while if the difference increases rapidly, the speed of the two falls below that of the current. It is evident that the many advantages of the chain (except that of draught) in going up streams disappear in coming down. The heavy chain cannot be allowed to pass over the gear in the boat at too high a speed, and thus it is not desirable to give the convoy as great a rate as that of the current; but, on the other hand, if this speed is approximately maintained, the transit becomes dangerous, and if it falls below, it becomes impossible. From the foregoing considerations it appears that the most efficient system would include a boat adapted for chain haulage going up stream and as a tow in coming down.

The mechanical arrangements that have been devised to maintain the movement of the towing chain have been unsatisfactory and complicated. M. Bovet, a French engineer, has sought to grip the chain by the action of an electromagnet. The magnetized pulley is practically a solenoid with a soft steel core, the two ends of which are extended and brought close together in order to form the two flanges of the pulley. The pulley also possesses features of interest. The adhesion is sufficient to prevent slipping under any conditions that may occur. The first trials of this class of pulley were made with chain towboats built for service on the Seine, below Paris. Only one pulley was employed in the preliminary experiments. Our engraving illustrates an electric towboat for canals constructed for the Compagnie des Touages de la Basse Seine et de la Loire.

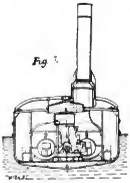
The first boat of this type with magnetic adhesion gear was tried and put on service by the towage company of the Basse Seine, in 1893. It was fully described about that time at the Fifth International Congress of Internal Navigation. (See the published proceedings of that congress; the Memoirs of the Société des Ingenieurs Civils, 1893; and the Revue Universelle, May, 1893.) Three other boats of a similar type have, more recently, been put in service by the same company, and on these several modifications suggested by experience have been introduced. As regards the towing machinery, the changes have been very small, but alterations have been made in the construction and arrangement of the boats themselves, so that they differ considerably from the earliest model. The most recent type is illustrated in Figs. 1 to 6. The section of the Seine on which these boats are running is of considerable depth, and advantage has been taken of this fact to supplement the chain haulage with a screw propeller, and the form of the hull has been modified to suit this auxiliary propulsion. As on all boats of this class where steerage is difficult on account of the action of the chain, two rudders are fitted, one forward and the other aft. The total length measured on the deck is 31 meters (101 ft. 8 in.), and the outside width is 5·470 meters (17 ft. 11 in.); the normal draught of water is 2 meters. The hull is divided into five watertight compartments by four bulkheads; forward there is a hold, and the accommodation for the deck hands, while aft there is a similar hold, and the living room of the machine hands. The engines are placed amidships, and the deck over them is raised 18 in. The construction of the hull and deck is very solid, as will be seen by reference to Fig. 7, where 1 and 2 are the forward and aft bulkheads, and 3, 4 and 5 are heavy double T transverse beams; 6 is a lattice stiffening girder. The girders a, b, with the transverse beams 2 and 3, inclose a hatchway, through which the boilers can be removed if necessary; c and d connect the transverse beams, 3 and 4, and serve as a means of attachment of the chain brake and of the tow hook. The girders, e and f, with the transverse girders, 4 and 5, frame the engine hatchway. The chain well is shown at g and h. The brake, k, and the main frames, l and m, connect the lattice gird-

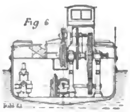


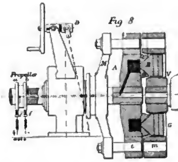
ELECTRIC TOWBOAT FOR CANALS—BOVET SYSTEM.

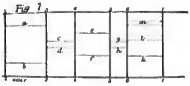
er, 6, to the forward bulkhead. The tow gear, that is the two cables by which the convoy is attached to the tug, is fastened to the lattice girder, 6. It is this girder, therefore, which has to resist the chief pull of the chain and the resistance of the tow. In the engine room there are two internally fired boilers with return flues, registered for a working pressure of 8 kilos. (114 lb. per square in.), and each with 50 square meters (538 square feet) of heating surface. A vertical compound engine drives gearing so arranged that it can transmit power to the screw or the chain apparatus. The system of transmission is shown in Figs. 2 and 3. That for the chain is from the main shaft to the driving pulley of the chain, by two toothed wheels keyed to the with the full tow. To facilitate this a shifting gear worked by hand is employed, by which high pressure steam is admitted direct into the large cylinder. It would be preferable on boats of this class to have an independent motor for the screw, and one for the chain, and the arrangement we have described was adopted only on grounds of economy; as a matter of fact, however, the single engine has satisfied all requirements. The chief defect is, that having available a much higher power than is necessary for chain haulage, the crew are tempted to run too fast, and so incur a serious danger of breaking the chain. But it is possible to check this by attaching a speed recorder on one of the chain shafts.

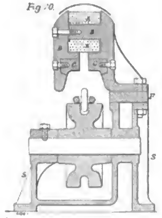
attached to the forward bulkhead; the conductors are laid within wood casings, and the resistances are placed on the right of the chain well. (c) An ejector used for filling and emptying the aft compartment of water ballast; for removing water from the hull and from the chain and pulley well; for washing the deck and chain run, etc. There is a combination of valves by which these various services can be effected with the steam pump of the main engine. Reference was made above to the water ballast in the aft compartment. When running on the chain this compartment is empty, and the boat is practically on an even keel. When running with the screw the compartment is filled so as to bring the stern down sufficiently for the screw,

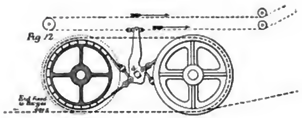


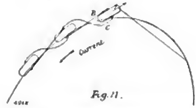












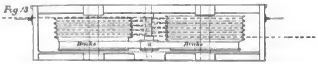


FIG. 14.

ELECTRIC TOWBOAT FOR CANALS—BOVET SYSTEM.

two shafts. As a general principle the boat is only driven by the screw in coming down stream, and the power required for this is higher than for the chain towage; the transmitted speed is therefore greater for the former than the latte[illegible] The engine is designed for working at different spe[illegible]he normal being 150 revolutions when driving th[illegible]nd from 70 to 90 when working the chain ger[illegible]eveloping 150 horse power at 150 revolut[illegible]tion of fuel is 2·2 lb. per horse power [illegible] from the chain might be a difficult op[illegible]y cause it became necessary to stop in [illegible] then start

There are also placed in the engine room the following apparatus: (a) A dynamo and motor for furnishing the current to the various magnetized devices. The engine has two cylinders, and may be worked single or compound; it can exhaust into the condenser of the main engine or into the air, as may be most convenient. This installation furnishes from 30 to 40 amperes, with a consumption of 18 kilogrammes of steam per electrical horse power, when exhausting into the condenser. The maximum power when exhausting into the air is 60 amperes, but with a considerably higher consumption of steam. (b) A distribution board

which is 1·70 meters in diameter. The compartments on each side of the main engine have together a capacity of 11 cubic meters (388 cubic feet).

With the arrangements that we have described, when the boat is driven by the screw, the chain mechanism is thrown out of gear, the screw shaft clutch is coupled and the dynamo is stopped. When working with the chain the screw is uncoupled, though it is desirable to be able to couple it again rapidly and without stopping the main engine, either to keep the boat straight if the chain break or to run it together with the chain. It is true that at the slow engine speed necessary for the

chain haulage, the screw cannot do much to propel the boat, but the wash from the propeller is thrown against the rudder, and helps the steering in turning round sharp bends. In order to facilitate coupling up quickly, a magnetic clutch is added to the mechanical coupling.

The development of this magnetic clutch, of which a large number are now in use, was due to the experiments with the chain pulley already described. It has the advantage of great adaptability, and can be readily thrown on when running, without checking speed or setting up any shock. Such clutches are in service on engines up to 800 horse power, and working at 100 revolutions. Figs. 8, 9 and 10 give a good idea of their construction. In these figures V is the flywheel of the engine; A, M, D are the parts of the ordinary mechanical clutch; excepting that the piece, A, instead of consisting of two arms, is formed of a circular plate with two projections, in which holes are made for guiding the tenons, d. In this disk, A, is cut a circular groove that holds a wire coil, the two ends of which, passing through the center of the main shaft, are led beyond the shaft bearings to two terminals, a, b. On this same disk are fixed the two jaws, c and d, the whole, A, c, d, forming an electromagnet that can be excited by the coil. The armature of this electromagnet is a circular crown of wedge section, B, placed against the flywheel, V, of the engine; it is held in place by four sets of Belleville springs, arranged as shown in Fig. 9, and is capable of attraction to the surface of the electromagnet and of being held there when the latter is excited. This piece, B, is driven by the flywheel through two projections that slide in grooves cut in the flywheel. When the electromagnet is excited the armature becomes fast in the magnet, and the coupling is complete without the action of the mechanical clutch.

The chain traverses the deck longitudinally in the usual manner. Forward and aft are two switches, adapted to suit the oblique movement of the chain, and leading it to fixed vertical rollers, between which its position becomes fixed. Between these pulleys and the towing gear, the chain passes over a series of rollers placed in a watertight trough that collects the drippings and detritus brought up from the bottom. The main tow pulley is almost hidden beneath the deck. One side of the casing containing it is placed far enough away to insure complete magnetic insulation; the casing itself is of wood, lined with zinc. The small taking-off pulley, which has but little work to do, is mounted on the end of its shaft, and has one face thoroughly insulated. The leading-in pulley has, on the other hand, to resist a considerable strain; on account of the change in direction it gives to the stretched chain, it is mounted on a shaft carried in strong bearings on each side. It is an ordinary cast iron pulley, but it can be magnetized, and can be converted into a driving pulley by means of a toothed wheel on its shaft, gearing into another toothed wheel on the main shaft of the towing gear, which transmits movement to the taking-off pulley. The toothed wheel on the leading-in pulley shaft can be shifted so that the pulley can be either idle or driving; it is magnetized only in the latter case. The object of the arrangement, which is not really necessary, is to obtain greater adhesion if required. Directly aft of the towing gear is the chain well, which is introduced to keep on board a certain amount of slack. To the well is added a chain brake that regulates the rate of discharge, and the quantity kept in the well. It consists of a straight electromagnet, placed above the chain run. Fig. 10 shows it in transverse section. It is placed very close to the passing chain, and when magnetized attracts the latter; the rate of travel then depends on the degree of magnetization, and the weight of the chain aft of the brake. On the frame of this brake is mounted the hook used for attaching a tow when the boat is running with the screw. An examination of the drawings will show that when it is desired to take the boat off the chain the latter need not be divided, but the whole of the towing gear can be shifted to one side of the boat. For this operation it is only necessary, by means of the brake, to accumulate three or four meters of slack in the chain well, and to put stoppers on the chain at the switches fore and aft. Of course the boat has to be stopped, but the whole operation does not take more than ten minutes.

The captain has under his hand the steering wheel of the after rudder and the commutator lever, with which he can turn on and regulate the current for the various magnetic devices. The main and taking-off pulleys receive five, twenty-five or thirty-five amperes; the brake can receive three, six, nine or twelve amperes; the magnetic clutch of the screw is thrown in by pressing a button, without any variation in the current. The forward rudder is in charge of one of the crew, who also controls the various towing devices, about which a word should be said. The convoy is always attached by two crossed cables, and these require some manipulation, to insure its taking a proper course. Fig. 11 is a diagram showing a tow passing round a bend; the sketch shows the operation, the cable, B, being tightened and C slacked; if the bend were in the other direction, the maneuver would, of course, be reversed. Usually very large and heavy hemp cables are employed (they weigh five and one-half kilogrammes per meter on the boats of the Compagnie des Touages de la Basse Seine et de l'Oise), and there is a good reason for this practice. It is impossible to start a convoy without throwing a sudden and great strain on the cables, and as the barges are usually of light construction, they would be speedily damaged. But the heavy cables absorb the effect of this shock to a remarkable degree, and thus provide a simple but very effective method of protecting them. On the boats we are describing, an interesting experiment has been made by the use of light steel cables, combined with an elastic device, to absorb the shock. This arrangement is shown in Figs. 12 and 13; it consists of a double grooved drum, similar to the old chain haulage pulleys. The cable takes four half turns on each drum, and the end is rolled around a supplementary store drum. The two drums are held up by means of a brake, the arrangement of which constitutes the novelty of the system. As will be seen in Fig. 12, the brake consists of a band, lined with blocks of wood, and having its ends jointed to the head of a crank free to move around a vertical axis, a, and having a small amount of play in the direction of the tangent common to both pulleys. In this way the compensating action is automatic; the pressure is progressive as the boats forming the convoy are added, and as they move forward the required elasticity is obtained. When traveling the brakes are locked hard, and if it is desired to slacken one of the cables, it is sufficient to release the brake; the storage cable supplies the additional cable required, a light brake checking the tendency to unwind more than is required. On the towboat the bollards and storage drums are fixed under the deck, as is shown in the drawings, in such a way that all the necessary operations are controlled by four handwheels placed near the wheel of the forward rudder. Fig. 14 is a general view of the boat we have described, and shows the forward leading-in pulley, the towing apparatus and the leading-out trough.

THE MAGNETARIUM.

M. WILDE recently presented to the French Academy of Sciences an apparatus which he calls a magnetarium, and which is designed to reproduce the phenomena of terrestrial magnetism and the secular changes of the horizontal and vertical components.

The apparatus consists of two terrestrial globes, one of which revolves within the other. An insulated copper wire is wound around the inner globe, the axis of which makes an angle of 23·5° with that of the outer one, so that its equator revolves in the plane of the ecliptic. The interior surface of the globe is likewise provided with a winding of insulated wire, and the surface of the seas is covered with thin sheet iron, in order to cause a difference between the magnetism of the terrestrial and maritime regions.

The axes are provided with insulated rings, which revolve along with them. Copper brushes in contact with these rings cause electric currents to pass around the surface of the globes. By means of a train

THE MAGNETARIUM.

of epicycloidal toothed wheels, a slow differential motion is communicated to the internal globe, thanks to which there may be accurately reproduced the principal phenomena of terrestrial magnetism and the secular variations of the declination and inclination that have taken place for the last three centuries at London, the Cape of Good Hope, Saint Helena and Ascension Island.

The period of time that corresponds to a difference of one revolution in the rotations of the two spheres is 960 years, and the annual retardation of the electrodynamic sphere is 22·5′. This period comprises all the different secular variations of the magnetic elements upon the different parts of the terrestrial surface.

The apparatus likewise reproduces the various elements that follow: (1) The inequality of the periods of declination upon the same meridians in the northern and southern hemispheres as observed during the short period of western elongation at London (160 years) and during the long period of western elongation at the Cape of Good Hope (272 years) and at Saint Helena (256 years); (2) the simple displacement, in one direction or the other, of the dipping needle for the double movement, forward and backward, and of the declining needle, as it has been observed since the year 1723 in the continuous diminution of the dip for the British Islands during the motion of the declining needle toward the west and its return; (3) the changes of dip in an opposite direction upon the same meridians in the northern and southern hemispheres, as observed during the present period in the dip that diminishes in the British Islands and increases at the Cape of Good Hope, Saint Helena and on Ascension Island; and (4) the rapid increase in the dip in the vicinity of the Atlantic node of the magnetic equator (17 minutes per annum), as observed in the first place by Sabine in the Gulf of Guinea and at Saint Helena, as well as the western progression of this node itself.—La Nature.

TRADE MARKS IN THEIR INTERNATIONAL RELATIONS.*

IN early times manufacturers and merchants took the accumulations of months of labor to fairs, where such were disposed of in a few days—repeating the operation from year to year; but the modern methods of rapid intercommunication have made it possible for them to dispose of their products and purchases as rapidly as manufactured, or collected; hence the disappearance of the ancient fair, and the birth of the international exposition, where goods are exhibited not so much for the purpose of sale as for introduction.

The first international exposition was held in London in 1851, and was followed by an international exhibition in Dublin, 1853; an exhibition of industries of all nations in New York, 1853; a universal exposition at Paris, 1855; an international exhibition at London, 1862; the Paris universal exposition, 1867; and the Vienna exposition of 1873.

What was more natural than that manufacturers and merchants who had, at great expense, exhibited at these expositions should observe and discuss the perils which they ran by reason of want of protection to their marks? It was apparent that without such protection their display was for the benefit of the imitative in the country where the exposition was held. They also observed that goods bearing the same marks were sometimes exhibited by different parties from widely separated countries, and that the authorities were called upon by one to suppress the exhibit of the other.

The necessity for the international protection of marks wherever international trade existed was evident; but not until the exposition at Vienna in 1873 was the matter formally discussed at an industrial congress.

The discussion so commenced was continued at the congress concerning industrial property held at the Paris International Exposition of 1878. By resolution of that congress a committee was appointed to obtain the consent of the French government, or, failing in that, some other government, to take the initiative in calling an official conference of the commercial nations of the world to formulate a convention for the protection of industrial property. The French government happily took the initiative and a conference was held at Paris, commencing November 4, 1880, which drafted the convention for the protection of industrial property, afterward ratified at Paris March 20, 1883, with very slight changes only. This convention covers patents as well as trade marks.

At the conference of 1880 the following states were represented, viz., Argentine Republic, Austria-Hungary, Belgium, Brazil, France, Great Britain, Guatemala, Italy, Luxemburg, the Netherlands, Norway, Portugal, Russia, Sweden, Switzerland, Turkey, United States, Uruguay and Venezuela.

The Hon. William M. Evarts, Secretary of State, in his instructions to Mr. Noyes, minister to France, and to Mr. Putnam, minister to Belgium, as delegates, said:

"The subjects proposed for discussion are in a marked degree important to all countries whose trade and manufacturing industries have attained high development, and this country cannot but feel the liveliest interest in any conclusions which may advance and benefit its commerce and manufactures."

Mr. Putnam, at the conference, referred to the peculiar position of the United States, arising from the fact that power to legislate concerning trade marks was not specifically mentioned in the Constitution of the United States. The trade mark cases declaring the trade mark statutes of 1870 and 1876 unconstitutional had lately been decided in the Supreme Court and were fresh in the public mind. The conference favored the United States by inserting a special clause in the proposed convention to meet its case. This clause was somewhat modified in the convention as ratified. Our delegates took no part in the discussion concerning patents.

The convention was ratified on March 20, 1883, by the following only of the nations represented at the conference, viz., Belgium, Brazil, France, Guatemala, Italy, Netherlands, Portugal, Salvador, Servia, Spain and Switzerland. Salvador has withdrawn.

Since the ratification it has been adhered to by the Dominican Republic, Great Britain, Sweden and Norway, the United States, Tunis, Denmark and Austria-Hungary, with a proviso of legislative ratification.

The salient features of the convention (so far as relates to trade marks and trade names) are:

(Art. 2.) That citizens of each of the contracting states shall enjoy in all of the other states of the union the advantages, so far as concerns trade marks or trade names, that the respective laws thereof accord to citizens; they shall have the same protection as the latter, and the same legal recourse against the infringement of their rights, subject to the formalities and conditions imposed upon citizens by the domestic legalization of each state.

(Art. 6.) That a trade mark regularly registered at home shall be registered and so protected in all the other states of the union, subject to refusal only if the object for which it is asked is considered contrary to good morals and to public order. (Art. 8.) The trade marks shall be protected in all the countries of the union without registration. (Art. 9.) That every production unlawfully bearing a trade mark or commercial name may be seized on importation into those of the states of the union in which such trade mark or commercial name has a right to legal protection. (Art. 10.) That seizure shall be applicable to products bearing falsely the name of a stated locality when this shall be joined to a fictitious commercial name or a name borrowed with a fraudulent intention. (Art. 11.) That protection shall be accorded to trade marks and trade names at international expositions. (Art. 13.) That an international bureau shall be established at Berne.

Foreseeing the probable desirability of revision, it was provided in Art. 14 that "The present convention shall be submitted to periodical revisions for the purpose of introducing improvements calculated to perfect the system of the union. With this object, conferences shall take place successively in one of the contracting states between the delegates of said states. The next meeting shall take place in 1885, at Rome."

* A paper read before the New York Board of Trade and Transportation October 13, 1897, by Francis Forbes.

The conference at Rome was duly held, the United States being represented by Mr. Stallo, United States minister to Italy.

The principal amendment proposed was an addition to Art. 10, that every product bearing a false indication of origin should be seized on importation into any one of the contracting states; and that the seizure might also take place before shipment or after importation. Also for temporary protection of inventions, designs and models appearing at international expositions.

These propositions were not ratified by all of the contracting states, and therefore failed.

The United States adhered to the convention in 1887 and under an act of Congress (26 Statutes at Large, page 17) sent three delegates, Hon. Thomas W. Palmer, minister to Spain, and Messrs. F. A. Seeley and Francis Forbes, to the succeeding conference at Madrid in 1890.

The conference at Madrid, because of the failure of the propositions of the conference at Rome to receive universal assent and to be incorporated into the convention, adopted the expedient of subsidiary conventions and unions, which have gone into effect between the several powers which have agreed to them only.

There are two of these subsidiary conventions, both signed at Madrid April 14, 1891, viz.: One for the suppression of false indication of origin, i. e., the seizure of all goods bearing any mark indicating a place of manufacture or production other than the true place. Such goods are to be seized in the country of production, on importation into another state, or in the latter state, or, in case the laws of any state do not permit of seizure, such other remedies are to be taken for repression as are allowed by the laws of that country. (The latter clause was added at the suggestion of the delegates from the United States.)

Art. 3 permits the vender of goods coming from another country to indicate his name and address, but in that case the address or the name must be accompanied by a clear indication in legible characters of the country or place of manufacture or production.

The following nations have adhered to this subsidiary convention: Brazil, France, Great Britain, Portugal, Spain, Switzerland and Tunis.

The other subsidiary convention provides for the international registration of trade marks, to which Brazil, Belgium, France, Italy, Netherlands, Portugal, Spain, Switzerland and Tunis have adhered. Also Austria-Hungary, with a proviso of legislative ratification.

International registration under this agreement is a purely diplomatic affair. The citizen of a government adhering to the union applies to his government to register his mark for him at the International Bureau at Berne, and the bureau in turn forwards such mark for registration to the other states of the union. The fees are only those of the various governments, and in addition an almost nominal fee for the International Bureau. The registration being thus made is freed from any of the risks attendant upon the work of making separate registrations in the separate countries.

The convention of Paris of March 20, 1883, for the protection of industrial property is of the greatest importance to trade mark owners in the United States, since it makes provision for the time in the growth of their several businesses when they will overflow national bounds and become international.

Without any international agreement and with each government acting according to supposed local interest, the same trade mark might be used in many different countries, with the result of limiting the trade of each user of the mark to certain geographical bounds.

An example of what we mean recently appeared in the Belgium Trade Mark Journal, which publishes officially all registrations. In vol. 9, at page 43, occurs a statement of the registration of the trade mark "Okonit" for an insulating compound for electric cables, etc., by a German firm. Now, "Okonite" is a well known trade mark here for the same article, and is registered at the Patent Office in Washington.

Another example is that of two prominent starch manufacturers, one of whom has a trade mark registered and long in use in this country, but little trade abroad. His rival has commenced to use the mark in England but not here, and has applied for registration there, which is being opposed. It is said that, if the registration is granted to the applicant in England—who does not use it here—he can stop the manufacturer here from shipping to England. This is not an enviable condition for a future expansion of the trade of the originator of the mark.

These examples show the serious nature of the question of international registration, and of treaties to protect marks in their international relations.

A third conference under the convention has been called to meet at Brussels, Belgium, on December 1, 1897. This conference is held in France to be of such importance that numerous propositions for the amendment of the convention have been forwarded (according to newspaper reports) to the various chambers of commerce throughout the republic for their opinion. It should awaken the liveliest interest in our own manufacturers and merchants, also expressed through their boards of trade and chambers of commerce.

It is to be observed that the convention for the protection of industrial property contains the following article:

"Art. 15. It is understood that the high contracting parties respectively reserve the right to make, separately, between themselves, special arrangements for the protection of industrial property so far as these arrangements shall not interfere with the provisions of the present convention."

The United States has made special treaties in regard to trade marks with the following nations: Austria, 1871; Belgium, 1881; Brazil, 1878; Denmark, 1892; France, 1869; Germany, 1871; Great Britain, 1877; Italy, 1882; Russia, 1874; Servia, 1881; and Spain, 1882.

We are not alone as a nation in our interest in foreign trade, as is demonstrated by the various treaties to which reference has been made. All history now points to the reaching out of the civilized nations toward the uncivilized in order to supply the latter with the refinements of civilization in exchange for raw products. We have heretofore been principally producers of these raw products, such as wheat and cotton. We are now, however, producers of manufactured articles requiring the highest skill, it behooves us, therefore, to enter vigorously into all movements which will protect not only the marks of our own citizens, but those of other countries similarly situated. By this co-operation we shall deal fairly and honestly with our neighbors, which fairness and honesty will redound to our own advantage as a nation.

NEW DEPARTURE CHEMISTRY.

By Dr. E. C. TOWNE.

IN the initial issue for the current year of The Electrical World, Prof. Elihu Thomson had an article entitled "Fuel Energy into Electrical Energy," and the editor of the publication referred to the article as treating of "the direct conversion of fuel energy into electrical energy," "electrical energy direct from the energy of fuel."

Prof. Thomson stated the problem as that of "how to obtain an increased efficiency or a greater percentage of the potential work of a fuel as electric energy." He spoke of the steam engine as effecting "the conversion of the potential energy of the combustible into electric energy," and referred to the claim made for the Jaques battery that "as high as 85 per cent. of the energy represented by the solid carbon is thus converted into electrical energy."

"Fuel energy," "potential energy of the combustible," "energy represented by the solid carbon," and "electricity direct from coal," means carbon which will do two things: (1) Incandesce of itself by its own electricity, and (2) give off extra electricity. But the fact is that carbon is absolutely inert and passive, a fixed solid, and able to do nothing whatever of itself. These statements of Prof. J. P. Cooke's "New Chemistry," exceptional as they are, are perfectly correct:

"Carbon is peculiar in this respect: In all its conditions, whether of diamond, graphite or coal, it is one of the most fixed solids known. Even when exposed to the highest artificial heat it never loses its solid condition.

"Since carbon, in all its forms, is non-volatile, the molecules of the charcoal [burning in pure oxygen] cannot leave the solid lumps. They do not, therefore, go half way to meet the oxygen molecules, but simply receive those which are driven against the surface of the coals. Hence the process depends on the activity of the oxygen molecules alone.

"The glowing particles of charcoal [finely pulverized, made red hot and sifted into pure oxygen], after they have become incandescent, retain their solid condition until the last atom of carbon is consumed.

"The material of the burnt charcoal is taken up into the gas atom by atom, actually absorbed by it as a sponge absorbs water. Every molecule of oxygen which strikes against the charcoal flies off with an atom of carbon, forming with it the molecule of carbonic dioxide."

The oxygen molecule is one of two atoms, O-O, and this molecule becomes O-C-O, but the physics of the operation is probably not that of absorption, or as Mendeleef, greatest of modern chemists, says, a carbon atom squeezed in between the two oxygen atoms. It is far more likely that the carbon atom hangs upon the oxygen molecule $\frac{O\text{-}O}{C}$, and that, just as ozone, $\frac{O\text{-}O}{O}$, is three-atom oxygen, with the third atom hanging on to the molecule, but not wholly incorporated, so our CO_2, or $\frac{O\text{-}O}{C}$, is carbonized oxygen, with a purely oxygen history before it, in the relation of CO_2 to plant life.

But this apart. What I wish to say here is that the energy of combustion, or of any union of oxygen with a combustible like carbon, or any attack of oxygen upon carbon, is wholly oxygen energy and is no carbon energy at all, and that all getting of electricity direct from combustion of any kind is getting it from the oxygen.

The Chinaman who, after watching the action of the cable car, said, "No pushee, no pullee—go like mad," is quoted by Prof. Lodge as a philosopher, with this declaration: "Remember that, whenever we see a thing being moved, we must look for the rope. Unless there is either 'pushee' or 'pullee,' there can be no action. And if you further consider a pull, it resolves itself into a push [as the pull of a horse by pushing against the collar to which the pulling traces are attached]. We may make this general statement: The only way of acting on a body directly is to push it behind."—"Modern Views of Electricity," p. 291.

The push of steam in the piston gives the pull of the railway train, but the initial push is that of the oxygen of combustion as it pours into the engine fire. How that push of oxygen gas against the atoms of carbon fuel can have the tremendous efficiency required to push the engine and train is the problem which a railway train presents. It is evident that the direct forward push of the mass of oxygen cannot amount to anything. There must go with this some other push incalculably greater, and this can only be (waiving exact explanation) the push of the electrical charge of the oxygen.

The oxygen molecule, by reason of its electrical charge, has the necessary push, and if we are to read actions aright, we must invariably note this push of oxygen, and on no account suffer the conception of "attraction" to intervene. Instead of saying "intense affinity for oxygen," we must say energetic intensity of oxygen to unite with, to seize and hold fast, or to seize and carry away. So, also, if we note what action occurs in electrolysis, we must see electrical charge increasing the push of oxygen and throwing it back upon the anode. In the storage battery, oxygen electrical push is held in leash on the peroxide. It is a survival of the false "attraction" view which causes Thompson to ascribe "high chemical activity" to the hydrogenated lead, and to tell us that the cell does not store electricity, but rather stores energy in the form of chemical work. The energy is nothing else but the electrical charge of the oxygen of the peroxide. Electricity was driven into the peroxide, and the same electricity flows out again. It is oxygen push, at any rate, and it is hardly less plain that the push is electrical. "Chemical work" and "energy" mean nothing. We are using sound sense in seeing that oxygen push is the thing, and once that we see this, we may almost take for granted that this push is electrical. It is only dreadfully poor thinking which permits us to say that a cell which we have loaded up with electricity, and out of which we can get that same electricity, is not a storage-of-electricity cell.

And when we correctly note the electrical character of sun energy, we must also note that it is invariably related to oxygen, and not to carbon. If we remark the immense part played by the so-called carbonic dioxide in supplying, by way of entrance into their leaves, the chief substance of all plants, we must take care to see how the oxygen molecule and the sun co-operate. In the first place, pure oxygen is every moment the breath of life of the plant, precisely as of the animal; and it is by its own push that the oxygen beats into the protoplasm cells of the plant. It is not drawn in; not even in ourselves is it drawn in, for its entrance into the lung capillaries and the corpuscles of the blood; it pushes its own way; it alone is active; we are wholly passive; the whole of the driving energy of the animal system is oxygen push; the whole animation and order of vital movements in the plant is due to oxygen push; and no mistake can be greater than that of fancying that somehow the plant is run by sun energy apart from oxygen. Sun energy operates upon the oxygen and acts in the plant through oxygen.

Thus the oxygen which has come into union with carbon, each molecule of the oxygen carrying an atom of carbon, has its push intensified in sunlight; it pushes into the protoplasm cells of the leaves of plants, carrying its load of carbon; and the sun still augmenting its electrical intensity, it is helped to shake off its carbon and to push out into the air, with the wholly incidental result that the plant can use the carbon as food for its growth. The carbon benefits, and the plant, through the value of the carbon to it, benefits by the energy of the sun, but it is the oxygen of the carbonic dioxide on which the sun's ray especially act, helping it to push into the leaves of the plant, and then helping it to shake off its carbon load and escape into the air with fully restored intensity. Cooke states that oxygen and carbon combine in the proportion of 100 grains of oxygen to 37½ grains of carbon, and that every ton of coal burned yields 3⅔ tons of carbonic dioxide. That is to say, the work of burning a ton of carbon is done by 2⅔ tons of oxygen. The great new German steamship is said to have bunkers for 4,950 tons of coal. If the coal were pure carbon, this would mean 13,200 tons of oxygen to do the work intended by the amount stated of coal, and 18,150 tons of carbonic dioxide going off into the air through the carrying energy still left in the oxygen. It might serve a good purpose to give adequate attention to the tremendous weight of tremendously energetic oxygen implied by eight tons of oxygen to every three tons of carbon, and oxygen with carrying energy sufficient to keep its flight as a gas after every molecule has taken up an atom of the passive, inert carbon. "Lavoisier inferred," says Cooke, "that oxygen must be the chemical center in the scheme of Nature." Its electrochemical energy is what gives oxygen its supreme place. The driving energy of our fires and light-giving flames, and of all vital activity in both plants and animals, is the electrical charge carried by the oxygen of the air.

SEWING NEEDLES IN GERMANY.

THE sewing needle, though small, forms a very important article of commerce in Germany. While formerly England supplied that country with needles, this industry, according to the United States consul at Annaberg, has during the last few years developed to such an extent that the Germans are able to meet their English competitors, not only on the markets of the world, but in the British colonies and in England as well. The principal seats of the industry are Aix la Chapelle, Burtscheid, Iserlohn, Altona, Nuremberg, and Schwalbach. The factories of Aix la Chapelle alone produce 50,000,000 needles weekly. The following figures show to what extent the exports from Germany of these needles have developed. During the eight years from 1880 to 1887 the German export of needles of all kinds (embroidery, knitting, darning, sewing and sewing machine needles) amounted to 11,000,000 lb., of the value of £2,500,000. The following eight years make a still better showing. During this period the quantity exported was 15,000,000 lb., valued at £3,000,000. The enormous growth in the production of this article is due principally to the export trade to China, where Germany seems to entirely control the market. Other countries importing German sewing needles are British East Indies, France, the United States, Austria-Hungary, Italy and Turkey. In conclusion the American consul says: "Under the protection of their government the Germans have built up a needle industry which commands the respect of the world. At first they imitated the English methods of manufacture, but their superior technical training soon enabled them to discover the defects of the English machinery, and they adopted new and improved devices, and followed their own course of manufacture. The infant industry of a few years ago has become one of national importance. The manufacturers go into the markets of the world, preferably into new countries, and compete successfully everywhere."—Journal of the Society of Arts.

DANGER OF EXPLOSION AND FIRE IN THE MANUFACTURE AND STORAGE OF ALUMINUM BRONZE COLORS.

THE author observed repeatedly that the aluminum bronze colors became oxidized in the settling vessels to aluminum hydrate with evolution of hydrogen. The decomposition by water only took place if the temperature of the rooms in which were the settling vessels rose above 25° C. The evolution of hydrogen begins slowly, but in consequence of the heat of the reaction, becomes very vigorous. As there may be present in a settling vessel six kilos or more of the bronze color capable of evolving at least seven cb. m. of hydrogen, there is the possibility of a dangerous explosion by the formation of considerable quantities of inflammable gas in the rooms. By the admission of moisture and heat to packed aluminum bronze, evolution of hydrogen may take place, and if the packing material be inflammable, may lead to fire. Spontaneous combustion of aluminum bronze colors was also caused by friction or blows, due probably to small quantities of fat adhering to the powder. These phenomena were not observed with bronze colors made from copper zinc or copper tin alloys.—Zeits. Oeffentl. Chem.

Recent Books.

Experimental Science. By George M. Hopkins. This book treats on the various topics of Physics in a popular and practical way. It describes the apparatus in detail, and explains the experiments in full, so that teachers, students and others interested in Physics may readily make the apparatus without expense and perform the experiments without difficulty. The aim of the writer has been to render physical experimentation so simple and attractive as to induce both old and young to engage in it for pleasure and profit. A few simple arithmetical problems comprise all of the mathematics of the book. Many new experiments are here described for the first time. It is the most thoroughly illustrated work ever published on Experimental Physics. 840 pages. Over 780 illustrations. Seventeenth edition. Revised and enlarged. 8vo, cloth. $4 00

House Decoration. Comprising Whitewashing, Paperhanging, Painting, etc. With numerous engravings and diagrams. Edited by Paul N. Hasluck. (Work Handbooks.) 16mo, cloth. 160 pages, illustrated. London, 1897 ..... $0 50

House Plans. Inexpensive Country Homes. A handsome cloth bound portfolio containing more than 40 designs, with Floor Plans of Practical, Tasteful and Comfortable Colonial, Seaside and Suburban Residences, ranging in cost from $1,000 to $5,000. The illustrations are half tone reproductions from photographs of the completed dwellings. The location of the dwellings, the cost, the owners' and architects' names and addresses are given, and a description of the building, thus enabling, if desired, a personal inspection of the dwellings or correspondence with the architects. One large volume, 96 pages, 11 by 14, handsomely bound in cloth. New York, 1897 ..... $2 00

Klondike. A Manual for Gold Seekers. By Chas. A. Bramble. 18mo, cloth. 313 pages. New York, 1897 ..... $1 25

Physics. An Elementary Text Book for University Classes. By C. G. Knott. 8vo, cloth. Illustrated. 351 pages. London and Philadelphia, 1897 ..... $2 50

Picture Ribbons. An Exposition of the Methods and Apparatus Employed in the Manufacture of Picture Ribbons used in Projecting Lanterns to Give the Appearance of Objects in Motion. By C. Francis Jenkins. 8vo, cloth. 60 pages. Fully illustrated. Washington, 1897 ..... $2 50

Potters: Their Arts and Crafts. By John C. L. Sparkes and Walter Gandy. 12mo, cloth. 300 pages. Profusely illustrated. New York, 1897 ..... $1 25

Prospector's Field Book and Guide in the Search for and the Easy Determination of Ores and other Useful Minerals. By Prof. H. S. Osborn. Illustrated by 47 engravings. Second edition, revised, with a Glossary of Terms and other important additions. 256 pages. 12mo $1 50

Railways. The American Railway: Its Construction, Development, Management and Appliances. By various writers; with introduction by Thomas M. Cooley. New edition. Illustrated. Large 8vo, cloth. 456 pages. New York, 1897 ..... $3 00

Sugar. Beet Sugar Analysis. A Complete System of Instruction for Analysts in Beet Sugar Factories. By Elwood S. Peffer. 12mo, bound in oilcloth. 224 pages. Illustrated. 1897 ..... $2 50

Sunlight and Shadow. A Book for Photographers, Amateur and Professional. Edited by W. I. Lincoln Adams. Illustrated by Original Photographs from Nature. 8vo, handsomely bound in cloth, full gilt edges. 141 pages. New York, 1897. $2 50

Track. Railway Track and Track Work. By E. E. Russell Tratman. With over 200 illustrations. 8vo, cloth, 430 pages. New York, 1897 ..... $3 00

Valves. Slide Valves. A book for Practical Men on the Principles and Methods of Design, with an Explanation of the Principles of Shaft Governors. By C. W. MacCord. 8vo, cloth. 101 illustrations. 169 pages. New York, 1897 ..... $2 00

Valves and Valve Gearing. A Practical Text Book for the Use of Engineers, Draughtsmen and Students. By Charles Hurst. With numerous illustrations and 4 folding plates. 8vo, cloth. 235 pages. London, 1897 ..... $3 00

Volcanoes of North America. A Reading Lesson for Students of Geography and Geology. By Israel C. Russell. 8vo, cloth. 346 pages. Fully illustrated. London and New York, 1897 ..... $4 00

Witchcraft. Hours with the Ghosts; or, Nineteenth Century Witchcraft. Illustrated Investigations into the Phenomena of Spiritualism and Theosophy. By Henry Ridgely Evans. 12mo, cloth. 297 pages. Fully illustrated. Chicago, 1897 ..... $1 00

Wood Finishing. Comprising Staining, Varnishing and Polishing; with Engravings and Diagrams. Edited by Paul N. Hasluck. (Work Handbooks.) 16mo, cloth. 128 pages. Illustrated. London, 1897 ..... $0 50

Our large Catalogue of American and Foreign Scientific and Technical Books, embracing more than Fifty different subjects, and containing 116 pages, will be mailed, free, to any address in the world.

Any of the foregoing Books mailed, on receipt of price, to any address. Remit by Draft, Postal Note, Check, or Money Order, to order of

STEAM YACHT FOR THE ENGLISH AMBASSADOR AT CONSTANTINOPLE.

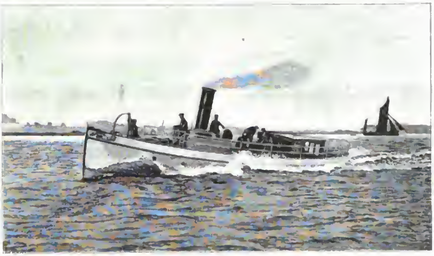
MANY of our readers, says the London Engineer, will no doubt be surprised to learn that although all the ambassadors of the chief Continental powers in Constantinople have for many years had very excellent steam launches attached to their embassies, the representative of Great Britain in that city has been without one until very lately, an omission which has been owing to the want of decision as to who—the Foreign Office or the Admiralty—should bear the cost of supplying and maintaining such a vessel.

The Thames Ironworks Company has completed a steam launch, or rather yacht, for the special use of his Excellency our ambassador at Constantinople, illustrated herewith.

The dimensions of this vessel are: Length on the water line, 60 ft.; breadth, 10 ft. 9 in.; depth, 5 ft. 5 in.; and water draught, 3 ft. 5¼ in. forward, and 5 ft. aft. She is fitted with compound surface-condensing engines, the high pressure cylinder being 9½ in., and the low pressure one 19 in. diameter, both with a piston stroke of 10 in., driving a single screw. The engine bed plate is built up of two longitudinal steel bearers extending the whole length of the engines, to which are bolted the cross main bearing brackets, made of manganese bronze. The columns supporting the cylinders are of forged steel, braced diagonally, as shown. The air pump is driven by a small crank overhung at the end of an extension of the main crank shaft, the feed pumps being worked by a worm on this shaft gearing with a worm wheel for reducing their speed, the ratio of the gear being 3 to 1. Great care has been taken in balancing the main crank shaft, with the result that, at a speed of 500 revolutions per minute, perfect steadiness is secured, without any perceptible vibration.

The steam distribution valves are of the usual type fitted to high speed engines, that on the high pressure cylinder being a piston valve, while for the low pressure a flat double ported valve is used, with the exhaust passing through its back, thus relieving it from face pressure, and rendering it practically a balanced valve. Cooling water is supplied to the surface condenser by a centrifugal circulating pump driven by an independent engine.

Steam for the engine is supplied by a Thames Ironworks patent water tube boiler of 18 square feet of fire grate surface, and 772 square feet of heating surface in the tubes, and like all of the similar make of boilers fitted in the Admiralty steam pinnaces made by the company, works without priming, and maintains a steady water level and steam pressure. The boiler is weighted to 185 lb. pressure per square inch at the safety valves, a forced draught at an air pressure of 4·2 in. in the stokehold being obtained by means of a fan driven by an independent engine. All Admiralty safety appliances have been introduced, thus making the machinery one of the most advanced examples of the small high speed type.



YACHT OF THE BRITISH AMBASSADOR AT CONSTANTINOPLE.

On the trial of this yacht, which took place shortly before she left the Thames for Constantinople, the mean speed realized on six measured miles, with the engines developing 861 indicated horse power, was 15·485 knots, and on a 2½ hours' continuous run 15·28 knots an hour, the mean revolutions of the engines being 512·85 per minute; the force of the wind being 2 and the sea smooth, hand picked Welsh coal being used.

As will be seen from the longitudinal section of the vessel we give in Fig. 1, there is good accommodation forward for the small crew required; and a very commodious saloon aft, with lavatory, pantry, etc., in addition to ample quarters for his Excellency the ambassador and any notables or friends to whom he may have to give audience, or meet at different times. The vessel will supply a long felt want at Constantinople, and will bear favorable comparison with any others running on the Golden Horn. She is built of two thicknesses of teak, with waterproof canvas between them, and is copper fastened throughout. Her keel, stem, and stern post are of English oak. She was designed by Mr. G. C. Mackrow, naval architect to the Thames Ironworks Company, and is an excellent speci-

men of the work turned out from the Orchard Shipyard and Engineering Works, Blackwall.

AMERICAN NAVAL ENGINEERS.

As our readers are aware, the engineers of the United States Navy have not been altogether satisfied with their position and the recognition they receive for their certainly arduous services. As there is no other navy so nearly akin to our own in regard to its personnel as that of the United States, an examination of certain proposals recently put forward will be of more than vicarious interest to us. The American naval engineers have found an able spokesman in the person of Professor Ira N. Hollis, who was formerly an officer in the corps of United States Naval Engineers. This gentleman has set forth his ideas in an article which appears in a recent (September) number of the Atlantic Monthly, a magazine published in Boston, U. S. It is safe to say that the views expressed by Professor Hollis have the support of, at any rate, a large section of the corps to which he formerly belonged. It is said that the propositions set forth were submitted to the Navy Department at Washington before the article appeared and that the Secretary (Mr. Long) and Assistant Secretary (Mr. Roosevelt) of the United States Navy are both very much interested in the matter. This naturally does not mean that the scheme has official sanction, and it is, of course, impossible to say what view the United States Congress may take of the matter. The position of the line officers—who correspond to our executive officers—is not altogether cordial toward Mr. Hollis' proposals, a fact which might be anticipated from the nature both of the proposals and the line officers. A number of the latter holding high rank have written to the department protesting against the adoption of the suggested plan. Nevertheless, we are informed, some of the younger and more thoughtful of the executive branch think well of the scheme, or at any rate think reforms on the lines indicated might be advantageous to the efficiency of the United States Navy.

So much by way of preface, but before proceeding to examine Mr. Hollis' scheme it may be remarked how strange it is to find the professor, in dealing with the navy of so modern and "go-ahead" a people as the Americans, opening his article with the statement that the last few years "has marked the complete break, perhaps forever, with the old line-of-battle ship, dependent for its motion upon an unreliable element, and the adoption of the powerful hull driven by a machine whose reliability depends only upon the care and foresight of men;" in other words, the United States has now steamers in place of sailing ships for the line of battle. Now, it would hardly more enter our heads in this country to emphasize this fact than it would to state that the Household Troops are no longer armed with bows and arrows, yet we organize the personnel of the navy very much as if James Watt had never lived and we were still in the glorious old days of "Nelson, Hood and Collingwood," when ponderous three-deckers sailed leisurely into action, and then lay, yard arm to yard arm, blazing away for hours until one or other had had enough of it, or there was a chance to board and settle the matter out of hand. In frigate actions it was somewhat different; but, heroic as these generally were, they constituted only the skirmishes of the seas, and had but small influence on the fate of nations. But even if the "motive power" had played ever so important a part in the decision of sea fights, the difference between then and now is that formerly the executive officers were thoroughly masters of the whole "mystery" of the propelling agency, whereas nowadays a captain in the engine room is about as useful as a marine at the weather earring. So far as we can judge, our emancipated and non-aristocratic cousins in America are little if anything ahead of us in this matter, and perhaps Mr. Hollis does well to remind Americans that they too have a steam-driven navy.

Mr. Hollis is commendably plain spoken in dealing with his subject. "For thirty years," he says, "there has been a struggle between the line and the staff of the navy; or between those officers who may succeed to the command of ships and those who may not. This struggle has developed the greatest bitterness between the line and the engineer corps." He goes on to point out that "the men in the compartments containing guns and ammunition and the men in the engine and boiler rooms must stay." They are both essential. "They belong to the fighting machine." It is further of paramount importance that "they must work in entire harmony toward the same ends," not only that they may live in peace among themselves, which is most desirable, but also "to attain the highest qualities of the ship." It is apparently in the American Navy, as in the English service, that "questions between the line and the engineers are carefully avoided at well regulated mess tables;" but it will be seen that such questions exist, and are of a very burning nature. Mr. Hollis compares the situation to being "penned up in the crater of a volcano," and attributes to this cause the reason of many graduates of the naval academy having left the service.

The situation is not so acute as this in the British Navy, but the conditions are somewhat different in regard to the national character and aspirations. In the United States the line and staff are brought up together until they enter the service, being graduates of the same school. There is no quarrel so bitter as the quarrel between brothers, and so it is that a sentiment of equality having been planted during the period of pupilage, it is very difficult for one branch to give way to the other in regard to accepting a position in which it must always receive and not give orders. This is the chief circumstance in which the training of the personnel in the navies of the two nations differ. With us the executive and engine branches are educated apart. Keyham never thinks it has the same function to perform as Dartmouth, and both branches enter the navy with a well defined status, which, in itself, is a great protector of harmony. Under existing conditions of service we prefer the English plan.

Mr. Hollis would put an end to the undesirable state of affairs in the United States Navy by the often suggested plan of fusion. "The only solution of the matter lies in fusing together the line and the engineers, and in making them all the line, except a small number, selected for technical attainment in engineering, to do the duties of chief engineers on board and on shore. All officers except the chief engineer, surgeon and paymaster would then be available for deck or machinery duties. . . . The navy could not fail to gain enormously by the greater engineering knowledge of the commanding officer and the increased interest of the chief engineer, in whose hands must be placed everything connected with machinery, whatever its nature, on board a ship." In regard to the last sentence, it will be gathered that the functions of the American line officer are already more of an engineering nature than is the case with the executive officer of the British Navy. In our service the engineering branch is responsible (it is true, to the executive) for all the mechanical and constructional parts of the vessel, including watertight doors and double bottoms. Later on, Mr. Hollis says: "Let the commanding officers become engineers, and let engineers rule our ships; then all fears will be dispelled, and the navy will quickly become a unit;" the fears referred to being those attributed to the line officers that "the engineers wish to command the ships."

It would savor of impertinence on our part were we to attempt to decide what is and what is not desirable for the United States Navy, but we think that the most ardent advocate of "fusion" will agree with us when we say that the author of the article has proposed a very difficult and thorny programme. He has, however, the courage of his opinions, for at the end of the article he gives thirteen suggestions for carrying out the scheme he advocates. It will be fairer, perhaps, if we give these in full.

1. To make the course at the Naval Academy the same for all cadets, with a strong emphasis on engineering.

2. To give all graduates, except those entering the marine and construction corps, commissions as ensigns of the line.

3. To require all line officers to spend their first six years at sea, equally divided between responsible duties on deck and in the machinery department.

4. To permit any line officer to specialize in engineering during his second six years as a commissioned officer, and at the end of that time to transfer him to the engineer corps through examination in engineering.

5. To require at least one officer of the engineer corps on every ship, and to place under his charge all that pertains to machinery on board, including the men required for engineering matters.

6. To give all watch duties connected with repairing and driving machinery to line officers under the direction of the chief engineers.

7. To promote all officers of the line and engineer corps at the same rate and to the same ranks.

8. To make the total number of line officers and engineers together what it is now by law, with a minimum of about 100 officers in the engineer corps.

9. To regulate the flow of promotion by permitting a limited number of officers to retire after thirty years' service.

10. To provide a "reserve list" for officers who do not reach command rank young enough to be effective.

11. To promote all ensigns after three years' service in the grade.

12. To transfer to the line all officers of the present engineer corps who have held their commissions less than twelve years.

13. To establish a general staff in whose hands shall be placed all matters connected with the preparations of war.

It will be seen that Professor Hollis' proposals take a wide range, and it is questionable whether he has been wise in this respect, for he has given many opportunities for those opposed to him to attack on side issues. The main proposition, however, is clear enough; it may be summarized in the word "fusion." "Let the commanding officers become engineers, and let engineers rule our ships," he says elsewhere. Now, we have had proposals something on these lines in regard to our own navy, but they were not nearly so comprehensive as the scheme of Mr. Hollis, and they have borne no fruit: fortunately so, for it was suggested to give executive officers a superficial knowledge of engineering subjects, in order that they might have a greater semblance of authority in the engine room. Thus it will be seen that even the executive branch could not altogether blind itself to the absurdity of existing conditions; and no doubt executive officers felt that power and dignity would some day pass out of their hands into the hands of those having knowledge. The scheme they proposed was, however, so absurd and untenable that there never was a prospect of its being put into force. Mr. Hollis, it will be seen, would proceed on very different lines.

No reasonable person will deny that the officer in supreme command of a modern warship would be better equipped for his duties had he a knowledge of all parts of the vessel—including the propelling machinery—such as the captains of past eras had. The sole question that remains is, therefore, whether it is within the bounds of reasonable anticipation that such knowledge can be acquired without detriment to other qualities absolutely essential to taking a ship into action. Mr. Hollis appeals to "the teachings of history" in support of his contentions. He draws a most interesting parallel based upon what occurred in the English service 400 years ago. Before the sixteenth century the sailor occupied a somewhat similar place to that of our engineer, and the soldier took the place of our sailor. That was when seamanship, as we understood it, did not exist, and ships were little more than hulls, which were useful only for bringing soldiers to a hand-to-hand fight. The discovery of the art of sailing on a bowline, or beating to windward—which took place about the era of Sir Walter Raleigh—and the use of guns afloat altered all this, for seamanship thus became an art, by the exercise of which a military advantage could be gained. The man who could maneuver a ship thus held the key of the situation, and gradually, but not without a struggle, the sailor asserted his superiority afloat, for his knowledge of seamanship by no means detracted from his fighting qualities. The contest for supremacy was long and bitter, lasting, Mr. Hollis says, for over two centuries, but it gradually died away, being obliterated by a process of "fusion," such as is now recommended. "Some of the soldiers learned seamanship, some of the sailors learned the handling of guns, so that it was seamanship rather than the sailor that captured the command."

It was in virtue of this "fusion" that England gained the mastery of the sea, and to it Mr. Hollis very rightly attributes our victories in the Elizabethan era. Our fleet was intrusted to sailors—Drake, Hawkins and Frobisher—while the Spaniards clung to the ancient system of soldiers in command. "The poor equipment of the Spanish ships (of the Armada), and the ease with which they were rounded up, like a herd of cattle, forms one of the most melancholy pages of history," says Mr. Hollis. Englishmen naturally take rather a more cheerful view of the matter, but that does not affect the argument. Nothing, however, is easier than to misapply the teachings of history, and it by no means follows that because the navigating sailor and the fighting man of 300 years ago could be "fused," the captain and chief engineer of the present day can be welded together with equal success. The whole tendency of modern advancements ashore and afloat is toward specialization and division of labor. The problem of civilized existence is so complex, there are such vast stores of accumulated knowledge to be acquired, that life is not long enough to enable a man to become efficient in more than one branch. In the yard arm days there was one sort of gun, one sort of gunpowder, and but few sorts of shot. Small arms—smooth bore, pike and cutlass—were equally simple. Navigation was not more difficult to master—it was more uncertain in practice—than it is in the present day; but now we specialize into gunnery lieutenants, torpedo lieutenants, and navigating lieutenants, with whole systems of sciences to learn, and furthermore, a science of naval strategy and tactics such as the mast-and-sails commander never dreamed of. Even in the sailing days the maneuvering of the ships was left to the master, who remained as a relic of the old struggle between sailor and soldier, to which reference has been made.

So much may be said against the "fusion" scheme Mr. Hollis proposes, but the objections are by no means final. In support of his suggestions it may be said that, with the exception, perhaps, of strategy and tactics, the whole duties of the executive officers—gunnery or torpedo—are based on engineering science, all branches of which have a common foundation of elemental principles; and even strategy and tactics depend on the machinery department. Whether, therefore, the complete naval officer—at once steam engineer, gunnery expert, torpedoist and navigator—be possible is the question that has to be solved. It is no good for him to get a smattering of steam, just enough—as some now have—to make himself ridiculous. He must go honestly through the mill, and know his engines and boilers as he knows his guns and torpedoes, and that is a question of time. We cannot afford to have naval officers growing into old men before they have learned their business.

Whatever training the commander of a ship may go through, there is one thing certain, his place in time of battle cannot be in the engine room. Therefore, the captain of the ship can never be, at the same time, the chief engineer, whatever his previous training and his engineering accomplishments may be. If, however, the captain cannot be the engineer, the engineer can become a captain; and, indeed, the present regulations which put an engineer officer under the orders of a gunner or a boatswain, in absence of a commissioned executive officer, are an anomaly which should speedily disappear.

There is one other point to which we would make reference, although it is not dealt with in Prof. Hollis' contribution, before concluding this article. We refer to the question of titles as apart from rank. In our own navy all engineers, from the engineer in chief downward, have no title or designation in virtue of their office, standing on the same platform as ordinary civilians in this respect. In the United States it is somewhat different, as there naval engineers holding high office are allowed combatant titles; for instance, the chief engineer of the United States Navy is known as Commodore Melville. At first sight this seems a small matter, and for our own part we have always considered the profession of the engineer so honorable that it carried distinction sufficient in itself. In the navy, however, there is doubtless more to be said, especially in regard to vessels serving abroad. In foreign countries it is customary for naval and military officers to be addressed by the name of their rank; that is the distinguishing mark of "an officer and a gentleman." If, therefore, a naval lieutenant and a naval engineer are in foreign society, and the engineer is simply Mister Jones, while his brother officer is Lieutenant Smith, the former gets very small consideration, and no doubt people often wonder whether he has any right in the drawing room at all. This is annoying even to the most philosophically inclined engineer, and though those not subject to the same disadvantage affect to make light of these matters, we have noticed that captains, and even admirals, are not overpleased if their rank is forgotten. The fact is the great inducement to the majority who join the combatant services is not the prospect of high pay and material advantages, but the honorable distinction and social prestige attached to the holding of a commission, and of this the military prefix is the outward and visible sign. As there are gunnery lieutenants, torpedo lieutenants, and navigating lieutenants, why not engineer lieutenants? It is said the engineer is not a combatant; that is a fiction. The whole war ship is a weapon of offense, and in handling the engines the engineer performs an act of fighting below as much as the captain does when he works the telegraphs in his armored conning tower on deck—especially if ramming operations are in contemplation—or as the torpedo lieutenant does when he directs the operating of a submarine torpedo discharge, also below the water line. The engineer officer wears a sword and we should like to ask whether, in the case of his ship being boarded, he would be expected to tamely submit to his engines being interfered with by the enemy so long as the colors were at the mast.—London Engineering.

The largest locomotive in Europe, and probably in the world, has just been completed at Liége to the order of the Belgian government. It is built on the compound system, having four cylinders, two each of high and low pressure, with respective diameters of 32 in. and 20 in. The wheels, of which there are twelve, have a diameter of 52 in. The extreme length of the locomotive is 55 ft. 6 in. and its weight is over 200 tons.

THE MANUFACTURE OF BRIQUETTE FUEL.

DURING the last two years there has been an abnormal supply of small coal on the market, which has partly been absorbed in the manufacture of coke, partly used in ordinary industrial undertakings and partly resolved into the form of briquettes. Nevertheless, the supply has been so much in excess of demand that in many districts small coal has been sold at perhaps not more than half of the cost of production, assuming that cost to be—as it really is—the same for small as for large coal. Increasing attention is now being given to the use of such coal for the manufacture of briquettes, which have been found specially well adapted to locomotive and shipping purposes, and can be exported to greater advantage than almost any other form of fuel. Much, however, still remains to be done in this direction, and the moment, therefore, appears to be opportune for reviewing the development of briquette fuel and making suggestions affecting its manufacture and applications in the future.

Like many other inventions and applications, it is difficult to fix either the period or the place of the first practical employment of a moulding process for the manufacture of small coal into bricks with the admixture of coal tar or bituminous matter. The first name extensively connected with the subject in this country was that of Mr. Warlich, who applied the process in South Wales with considerable success. About 1853 Messrs. E. and B. Johnston, of Chester, were the makers of some sets of mixing and moulding machinery employed in the North Wales coalfields, but except in the principality, very small use was made of the system.

On the Continent more general use has been made of methods for the consolidation of coal slack. Extensive use was made of it as a locomotive fuel within a few years after the first lines were opened on the Continent, and its employment may be said to have been general before 1850. The machinery for mixing and moulding now most generally employed in France and Belgium is that suggested by M. Evrard, and extensively used in the St. Etienne coal district, models of which were shown at the first Paris exhibition. This system embodied a principle borrowed from an English patent of earlier date for the consolidation of peat or coal by pressing it through a cylindrical untapered tube, relying on the friction of the mass in passing through for the resistance necessary to give the required compression to the fuel. M. Evrard used a vertical shaft with a single eccentric or cam acting in succession on a number of horizontal rams ranged radially around it. As these rams reciprocated they allowed portions of the mixture of coal dust and tar (a mixture effected at a temperature of about 300°) to fall before them, which, on the forward stroke, they pressed through the tubes into which they worked and formed the briquettes.

Modifications of ordinary brick machinery having more or less power of giving compression have been extensively used both on the Continent and in Great Britain at different times. These blocks have largely been made of poor Belgian coal, the cementing substance being the pitch resulting from the distillation of coal tar. The materials having been ground very fine and especially well mixed and compressed, the blocks were coked in a muffle furnace for subsequent employment in metallurgical processes. The same plan has been employed extensively in Paris for the manufacture of the artificial charcoal called Charbon de Paris—a substitute for wood charcoal made from charcoal dust of peat and wood in about equal parts, associated with from 5 to 8 per cent. of pitch, which is, however, volatilized in coking, leaving a hard, dry charcoal block.

According to recent information,* the Blanzy Company was the first in France to make briquettes, their works commencing in 1845. The original plant consisted of hydraulic presses by which only one briquette was made at a time. Tar was used as the agglutinant, and the product had to be passed through drying stoves for the purpose of giving it consistency. New methods of mixing and increased facilities for large production rendered new machinery necessary.

The plant now employed consists of two factories, one having three Révollier presses and the other four Biétrix presses. With the Révollier presses the method of manufacture consists in taking the coal dust containing 14 to 15 per cent. of water from the draining tanks of the washing house and tipping it into a pit, from which it is raised by buckets to a hopper in the upper part of the works. From another pit dry pitch is raised in buckets to the same hopper. The buckets are so arranged as to deliver 9 per cent. of pitch to 91 per cent. of coal. After being mixed by passing through endless screws, the coal and pitch is "pugged" for eight or ten minutes in a pug mill. The mill is jacketed with superheated steam. The mixture then falls into the moulds, and is compressed by means of hydraulic rams, averaging from 142 to 156 lb. per square inch. This lasts about half a minute, and leaves only 4 per cent. of water in the briquette. After compression the patent fuel is left on a haulage chain for 40 minutes, when it is ready for loading. The three machines produce 240 tons daily.

With the Biétrix presses the coal, before being pressed, is dried to remove the large quantity of water which it contains. The coal and pitch are mixed in definite proportions, and carried by endless screws into a revolving reverberatory furnace. The mixture, after turning round from 8 to 16 seconds, is taken by an inclined creeper to the pug mill. It now contains from 6 to 8 per cent. of water, which is further reduced by the press, the pressure being 2,300 lb. per square inch. Each press makes 22 to 23 briquettes per minute, or an aggregate for the hour of 330 to 340 tons daily. An auxiliary press makes round or "cannon ball" briquettes.

The Biétrix presses only make one briquette at a time. The coal and ground pitch are raised by a Jacob's ladder to the upper floor of the factory, and each of them tipped into separate hoppers, two for the coal and one for the pitch. These hoppers deliv[illegible] rotary distributors, with recesses, moving at va[illegible] speed, and the proportion of pitch varying from [illegible] 9 per cent. The distributers deliver on to a [illegible] screw, which in turn delivers on to the middle of a [illegible] end endless screw, conducting the mixture into a reverberatory furnace with revolving sole, the two presses being fed by an arrangement of distributers, hoppers and endless screws. The mixture is delivered in the center of the furnace, where, owing to the rotation of the sole, it is seized by a mixing arrangement which stirs it while pushing it from the center toward the circumference. After remaining in the furnace from 8 to 10 seconds, the mixture both dried and heated falls into an inclined creeper, which raises it to the pug mill or mixing machine of the press, where it is subjected to a second stirring or pugging. The mixing machine delivers directly, by an adjustable outlet, on to the revolving table of the press, the recesses of which are filled as they travel underneath. After passing through the furnace, the mixture only contains from 6 to 8 per cent. of water instead of the 13 to 14 per cent. which it contained before. In order to regulate the pressure, the beam crosshead is articulated to a piston working in a hydraulic cylinder with valves. The press thus makes per minute from 22 to 23 briquettes, of a weight varying from 84 lb. to 87 lb., which are received on carriages and carried to the loading place. Rope haulage is often used to lead the briquettes directly to the shipping station.

There are numerous methods in use for the manufacture of briquettes, founded more or less on the description of presses employed. In France the principal types of press employed are those known as the Révollier, the Biétrix and the Zimmerman-Hanrez. As originally constructed, the Révollier presses made cylindrical briquettes; but, during the last few years, as much with the object of increasing the production as for giving the products a greater facility for stowage, the moulds have been modified so as to produce rectangular briquettes. The dusty slack, from 0 to 9 millimeters, brought from the draining tanks of the briquette washing floors in 20 cwt. wagons, is tipped into a pit and raised by a bucket chain to the upper floor of the works, these coals containing from 14 to 15 per cent. of water. A bucket chain placed opposite the former brings to the same hopper the pitch, broken by a Carr disintegrator. The dimensions of the buckets of the two chains, their number and their speed, are regulated so that the proportion of pitch shall be about 9 per cent. The mixture of coal and pitch passes from the hopper into an endless screw, which, after a preliminary mixing, distributes it to other endless screws, directly feeding the pug mills or mixing machines, which, about 8 ft. 6 in. high, with an internal diameter of 3 ft. 2 in., are steam jacketed and provided with an injection of superheated steam. After a mixing of from 8 to 10 minutes, the mixture falls through a movable door onto the mould that is being filled, where it is spread out and leveled with a shovel, the filled mould then passing on to be compressed. Large pumps are used to subject the water to a pressure often of 600 lb. to the square inch, and finished by that of small high pressure pumps, by which the water is subjected to a further pressure of 5,700 lb. per square inch, which, with a total effort of 540 tons on the hydraulic piston of 18 inches diameter, produces on the briquette a pressure of 142 lb. to 156 lb. per square inch. One of these presses can make from 8 to 10 tons per hour.

The formation of fuel blocks by the admixture of tar with small coal has the drawback of increasing the amount of smoke developed, as well as the disadvantage of a certain amount of disintegration which takes place in the furnace as the binding substance melts. It has, therefore, been from time to time proposed to substitute for bituminous matter glutinous, farinaceous, or starchy materials, and several patents have been taken out with this view. The first practical application of the plan is said to have been made under Barker's patent by the London Patent Coal Company, at Northfleet, and the system adopted was described by Mr. Bassett, C.E., about thirty years ago, before the South Wales Institute of Engineers. The small coal was tipped from the wagons into a chamber the bottom of which fell toward the center, whence it passed into a disintegrator and was reduced to one uniform size. It then entered a pug mill, into which was fed a continuous and regular supply of mucilage to be thoroughly mixed with the coal. This mucilage was composed of about 8 lb. of farina (potato starch) and 1 oz. of carbolic acid; the whole was mixed in about 25 gallons of boiling water, and resulted in a paste or liquid glue. The above quantities gave sufficient adhesive compound for the formation of a ton of artificial fuel, at a cost of about 1s. 2d. for the ingredient. After mixing, the blocks were formed in a brick or other moulding machine, and required from 9 to 12 hours to dry in a chamber heated uniformly to 300°. The advantages claimed for this fuel over that manufactured with pitch were that it gave considerably less smoke, and that there was no loss of efficiency in the furnace due to disintegration, as the action of heat tends to harden, instead of to soften, the farinaceous cement. On the other hand, the process was more costly than the ordinary one, in consequence of the cost of the mucilage and of the drying operation. When it becomes necessary to carry with more or less care and to pile in some order so low-priced an article as common fuel, the expense of such operations tells heavily upon profits, and the construction of chambers large enough to hold 50 or 60 tons of fuel spread out for drying is no inconsiderable item, to say nothing of the cost of maintaining them continually at a temperature of 300°.

At a briquette factory recently built in connection with the Fröhliche Morgensonne Colliery, near Wattenscheid, Westphalia, the slack is tipped into a storing tower, from which it is led to the point where its mixture with ground pitch is effected. The mixture is then led to a distributing hopper, and thence into two directly fired heating ovens. After the mixture has been thoroughly warmed, it is led to the Couffinhall presses, which produce briquettes weighing 6½ lb. to 11 lb., three presses turning out 175 tons of briquettes in a day of 10 hours. The larger briquettes are chiefly used for firing marine boilers and the smaller for those [illegible] ...ployed, [illegible] briquettes. Seaweed boiled down in water may be very advantageously used by colliery owners whose works are situated near the coast. The weed on being boiled for some hours produces a glutinous mass, and acts as a good binding material; it should be mixed with the coal dust in the pan. Pine sawdust, 7½ per cent., mixed with the coal dust before going into the pan, improves the quality of the briquettes. Any kind of sawdust may be used, but pine is the best. The quantity of each binding material necessary can be best ascertained by experiment, and presents no difficulty.

* Paper on the briquette factories at the Blanzy Collieries, present[illegible] the Chalon-sur-Saône meeting of the Société de l'Industrie Minérale, [illegible] Dupont de Dinechin.—From the Iron and Coal Trades Review.

REVIEW OF THE PROGRESS OF THE HALF-TONE PROCESS IN THE YEAR 1896.*

By Count VITTORIO TURATI, Milan.

THE last year has enormously contributed to the extraordinary progress of half-tone processes in recent years, though the end of it shows an undoubted standstill in research and advance toward perfection.

Apart from the numerous very immaterial experiences published, we need only consider here those results of general interest.

SCREEN WORK.

Commencing with screen photography, we must state now, as before, that among the many screen systems prepared and tried, the cross line screen—with equal thickness of line and spacing—maintains its high place always with advantage, and enables the best and surest results to be attained.

A multangular screen which has been suggested, consisting of two line systems, moving one on the other, has offered no special advantage in practical work. On the contrary, it makes the work more difficult for the operator by the detailed manipulation requisite.

The many proposed grain screens, also, do not fulfill the promises which we long anticipated of them. They give always coarse prints with raggedness in the fine details, and the numerous attempts to substitute the screen by direct transfer from a coarse grained collotype plate has likewise, from easily conceivable causes, not led to any practical results. On this subject we can best acquaint ourselves by reference to an article published not long ago by A. Albert.†

The new four line screen of Levy gives—as shown by samples kindly sent to the author by Mr. Levy himself—very excellent results. By reason of two of the lines of the screen system being much finer than the other two, we obtain (with correct exposure and treatment) only one dot in the high lights, whereas in the shadows two dots appear in the same area. This solves a problem on which many investigators have worked for several years, a solution built up on the fundamental principle of the chemical correction.

This interesting four line screen is, however, very difficult to produce in large sizes, the cause of which is, as can be readily conceived, that the four line system has to be brought to an exact mathematical correspondence, which imposes a truly enormous task on the excellence of the machines used and the skillfulness of the manufacturer. It is nevertheless to be hoped that the well proved genius of Mr. Levy will overcome the above named difficulties.

On the principles of using the screen and stops, much has been written this year, but all these articles have advanced nothing on the fundamental work of the previous year, 1895, or at any rate very little that is new. The method of focusing for the screen distance, first proposed by the author, has proved in practice exceptionally successful.

The treatment of the collodion negative should be, as far as possible, conservative; the chemical correction is, however, a safe and sure auxiliary means of making faultily exposed or developed negatives useful.

To correctly work after Eder's rules, which are built rather upon a theoretical foundation, presents too many difficulties to the practical operator. Unfortunately this holds good up to the present day, but the time may not be far distant when better craftsmen will make themselves so acquainted with the principles of optical focus that it will be absolutely without difficulties to them. The above mentioned articles are recommended for study, especially the treatise on screen distances (Atelier des Photographen, 1896, page 191). The author has brought his own photographers to this standpoint already.

PROCESS PLATES.

Dry plates on the market for screen work include several makes which are useful, but have not, owing to various disadvantages, popularized themselves generally in practical work; therefore, a really good plate would be acceptable to the professional worker.

Such a plate should show at least all the qualities of a wet collodion plate, and this has been attained already by the author, by a particular method. Professionals like Collardon, Aarland, Perutz, Hemsath, etc., have spoken in the highest praise of the quality and power of this new plate. Active preparations for its manufacture on a large scale, which presents no slight difficulties, are being made.

Relative to the preliminary experiments it may be stated that a large and peculiarly constructed machine has been built, which is already giving very good results. It is anticipated that next year—as building must be done—the production of these plates on a large scale will be carried out.

The Turati plate is a stripping plate, the stripping being done directly after flowing on a leather collodion.

A NEW PRINTING PROCESS.

The following is a printing process which permits of ordinary transfer, not reversed or stripped negatives (being thus especially suitable for half-tone dry plates):

We copy on a bichromated gelatine paper, which is developed in the ordinary way in warm water, and transferred to the polished metal plates. By burning in, the picture is hardened into an enamel, the paper carbonizes and the etching can be performed in the usual way.

The author has published an article on the chrome [illegible] ...ting processes, in which a good deal is said on [illegible] of the colloids; among other things, that

* [illegible] ...ac Year Book.

† "Photographen Zeitung," 1897, page [illegible].

gelatine putrified, respectively by means of acids or alkalies, and thus rendered soluble in cold water (metagelatine), is qualified in a high degree as a substitute for the inconstant fish glue.

ETCHING PROCESSES.

As regards the etching processes, the enamel process still maintains the foremost place. No other process, as regards beauty, freshness and brilliancy, surpasses the enamel etching. The quality of the results is not only due (as is generally believed) to the solidity of the enamel on the copper, but to the gradual penetration of the etching through the enamel film. This is for the most part the cause of the wonderful softness of the results obtained with it. The author first directed attention to this in an article on "Through Etching by the Enamel Process," describing a matter which had not been noticed before.

The author has also found that zinc which is crystallized and structurally changed by heating can be etched very well in specially prepared etching baths. Until now, the burning-in process has been regarded as impossible with zinc, because the ordinary etching baths have an insufficient and extremely irregular action on the modified zinc, and give therefore only rotten and coarse results. But we can, by using a mucilaginous preparation while etching with sedimenting acid solutions, etch even the most crystalline zinc deeply and smoothly. The acid proportion may be thereby very much higher, enabling us to execute a half-tone etching by this new method to the greatest perfection in two to three minutes. This new method offers besides the utmost safety and facility for the etcher.

The so called "cold enamel" processes, founded mostly on the employment of formalin and other mediums, before and after, have not proved satisfactory in practice, as might have been foretold.

RETOUCHING HALF-TONES.

Before closing, a few notes on retouching will not be out of place.

The negative retouching is as good as entirely suppressed. The main point is to secure properly prepared originals. For vignetting, clever operators use optical tricks only. They close the highest lights simply by using a suitably large stop, thus saving the retoucher the troublesome and time wasting stopping-out. If we are not well acquainted with this method, we can also do it by a short after exposure on the original without the screen interposed.

As to the retouching of the plates, we may mention only the interesting discussion developed at the commencement of this year, on the merits of pure half-tone and retouching in the woodcut manner. Without saying more, it is clear that with both methods, in the hands of clever people, excellent work can be produced, while on the other hand, botchers will produce in either case only bad and insignificant work. At all events, the pure half-tone process has arrived to-day at such a high state of perfection that such hand work, besides rendering an increase in price necessary (and there can only be found an excuse for it in certain subjects), is not now required. To-day, when on every hand—even in Japan—excellent work in half-tone photography is accomplished, it is a matter of surprise that it should be thought necessary to resort to such meretricious aids for producing satisfactory work. It is now, moreover, quite clear that this has been only an attempt to put out a lifeboat to save the mediocre wood cut from disappearance altogether. The time which has elapsed, although short, has already shown that this attempt has been futile.

MOUNTING AND FINISHING.

The router and modern machinery for mounting blocks have proved successful and readily find the widest utilization. Of course, such machines can only be employed in large, well founded establishments, being mostly imported from America and very expensive.

For large editions it is always best to face the blocks with copper or respectively with nickel. This is not difficult by galvanic means. Recipes for coppering the blocks with a simple solution are old and consist of an ammoniacal cyanide solution of copper. Nickel recipes of a similar nature also exist, but have been kept secret until now. The use of cyanide has its great inconveniences, however, and the author has studied methods of avoiding it entirely; in his atelier zinc blocks are now copper and nickel faced by means of quick acting, inexpensive and not dangerous baths.

PRINTING HALF-TONES.

So much on the production of half-tone blocks. As to the printing of the same, very little new is to be said. A good overlay, or better still, a well executed photo-mechanical relief overlay, is always necessary.

Very beautiful effects can be produced with tint printing. This tint can simply be smooth, or preferably from a prepared plate, under-printed in the shadows. The "photo-chemigraph" seems to be founded on a similar principle—a process which gives very beautiful results.

Experiments done by the author by over-printing single but opposite lined half tone blocks have rewarded him with very excellent results. One block is first printed in a pale tint, and then the other in a soft intense illustration color. The blocks should be produced by the isotype process, and be of exactly the same size; the dotting must be very exact to avoid disturbing patterns.

A COMPARISON IN THE METHODS OF WORKING BRASS AND ALUMINUM.

ACCORDING to the new price list of the Pittsburg Reduction Company, which went into effect on October 15, it will be seen that aluminum sheet, even in small quantities, is cheaper than brass if the fact of the difference in specific gravity is taken into consideration. This great reduction in the price of aluminum sheet will undoubtedly cause a very material increase in the demand for aluminum to replace brass, and a few suggestions regarding the relative methods of working brass and aluminum may prove of interest.

To commence our comparison, let us take up the question of what changes the manufacturer would have to make, who is now spinning articles of brass, in order that he could substitute aluminum in these same articles. The only real change that is necessary is a change in the lubricant used, as the lathe speed is practically the same as well as the tools; only a lubricant of vaseline should be used on aluminum instead of the ordinary lubricant which is used in spinning brass.

After a little spinning has been done, and the spinner has been able to determine the rapidity of "flow" of the metal, he will be able to handle it more quickly and easily than brass, for the reason that, with but few exceptions, aluminum sheet can be furnished of the proper temper to start with, so that when the article is finished it will be as stiff as it is possible to handle it. Whereas, in brass, if very much work is to be done on the metal, it is generally found necessary to anneal the brass between the successive operations of spinning in passing from one chuck to another. Thus time and labor are both saved in the spinning of aluminum goods.

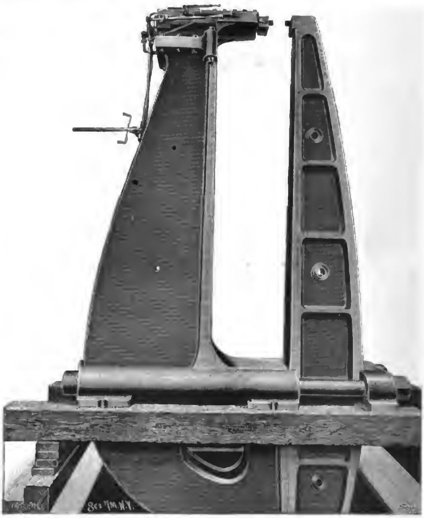
The same holds true in a comparison of spinning copper and aluminum, so that it can positively be stated that people having factories and machinery, and who are now manufacturing brass goods, can change the output of their plant to aluminum with practically no change in the machinery, and can make the articles they are now making out of brass out of aluminum in the future at a less cost, to say nothing of the money which would be saved by nickel plating where it is necessary.

In regard to a comparison of the stamping of copper and brass goods with aluminum, very little difference exists in the way of working these three metals. It would be well to note, however, that where one is using very thin aluminum sheet in the drawing press, the bottom of the male die should be so rounded that it will not cut or tear the sheet, which change can easily be made in any die at little or no expense. The lubricant in this case should also be vaseline, and not the oils or soap and water used on brass and copper.

Some factories to-day, that are both spinning and stamping aluminum goods, make the statement that they pay their men by the piece, and that they make more money and would rather handle and manufacture articles of aluminum at the same rate per piece than they would of any other metal. In regard to the drawing of very heavy sheet in presses, where it is only drawn in one direction, better results will be got by drawing the metal across the grain and not parallel to it. Aluminum, while of a short fiber, has a distinct one, similar to steel, running the length of the sheet.

A comparison of working brass or copper and aluminum on the lathe is also partically identical with all three metals. The greatest change here that has to be made is in the lubricant. For lathe work, or where any drilling or cutting is necessary, the best lubricant to use is coal oil or water. Coal oil gives the best results. Quite a large class of work, however, is performed dry, with excellent results. In some lathe work, such as the cutting of fine screws, etc., it may be found advisable to decrease the speed of the machine from the speed which would be used in turning brass, until the working of the metal is entirely familiar to the person handling it. After the particular peculiarities are established, which all metals possess to a greater or less extent, it will be found that aluminum can be worked in all cases more efficiently and rapidly than brass.

In starting a line of experiments with aluminum, however, it would be advisable to inquire particularly as to the relative merits of the alloyed sheets of aluminum and pure metal. In the majority of cases where aluminum fails to answer satisfactorily the purpose for which it is endeavored to be used, it is because the experiments have been conducted with the pure metal, whereas alloyed sheet should have been used. Pure aluminum compares with the alloys of aluminum exactly in the same way as pure copper compares with brass, and with but few exceptions, such as where electrical conductivity comes into the question or the effect of acid on the metal, is copper ever used; brass being considered the more desirable on account of its cheapness, as well as its greater strength and its general advantages. While the price of pure aluminum and the alloyed sheets of aluminum is the same in the majority of cases, it is found more advisable to use the alloyed sheet.—Aluminum World.



HYDRAULIC RIVETER.

LARGE HYDRAULIC RIVETER FOR LOCOMOTIVE BOILERS.

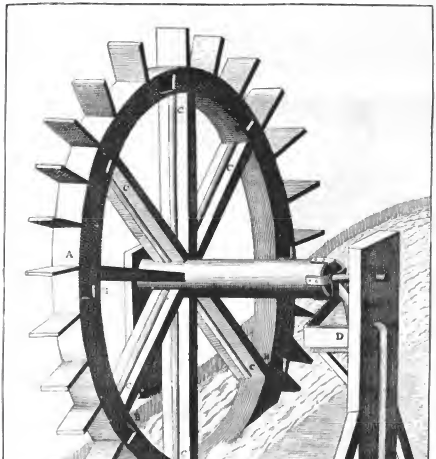
THE illustration above shows a long gap stationary riveter, specially designed for riveting a complete boiler shell at one plating. It has a gap of 16 ft. 6 in., and exerts a pressure of 50 tons upon the rivet. The main body is of cast iron of heavy box section, while the hob is of open section mild cast steel. The two are held together by a pair of very strong through bolts, having a large margin of strength to prevent any yielding under the pressure of the ram, so holding the hob very rigidly up to its work. The riveting head is bolted loose upon the main standard, and has a long projecting beak which permits of a steam dome being riveted to the boiler barrel by the machine. To enable the rivet snaps to get more closely into all corners, the cylinder slide and the top of hob are fitted with snap holders having six sockets—two right, two left hand, and two central, in two rows, one above and one below. By this means the machine is enabled to get at every rivet in a locomotive boiler or firebox, with the exception of one row in the top of the latter,

which, however, can be riveted by a special appliance if desired. The cylinder and slide are in one mild steel casting, bushed with gun metal and provided with large planed guide surfaces. The slide is held down in its guides by a pair of planed steel bars secured by set bolts. Great economy of water is secured by a special arrangement of water-saving gear, which causes the slide to be run out until the snap touches the rivet, the cylinder meanwhile being filled from an overhead tank. As soon as the snap touches the rivet, pressure is admitted to the cylinder to complete the operation. We are indebted to the London Engineer for the cut and copy.

MACHINE FOR RAISING WATER FROM A RIVER TO THE HEIGHT OF THE HALF DIAMETER OF A LARGE WHEEL.

The fellies of the large wheel, A, must be so constructed that they shall be hollow within, and that, being separated from each other, they shall form so many boxes capable of filling with water in passing into the river. To this effect, an aperture is made in them at B, that is to say, at that part of each felly that rises first when the wheel revolves; and, in order to cause them to raise water to where it is desired, there is also formed in them apertures at C into which are fitted pipes that extend along the spokes of the wheel, and then along its axle, and end in the reservoir, D, into which they empty the water from the compartments of the rim in measure as they rise above the half diameter of the wheel.

As the current of the river causes the wheel to revolve through the paddles with which its rim is provided, the fellies of the latter succeed each other continuously, take up water from the river and carry it in abundance to the height that has been proposed, that is to say, to the reservoir, D, which is at the level of the half diameter of the large wheel, A.—From Recueil d'Ouvrages Curieux de Mathematique et de Mécanique.



MACHINE FOR RAISING WATER FROM A RIVER TO THE HEIGHT OF THE HALF DIAMETER OF A LARGE WHEEL.

Owing to the death of William L. Winans, the American millionaire, who died on June 25, his two "cigar" yachts, which have been moored in Southampton Water for twenty-five years, will be sold. Enormous sums of money have been spent in experiments upon them, but few people have seen them under way.

THE COMMERCE OF THE GREAT LAKES.*

By Charles E. Wheeler.

The disastrous panic of 1893 was not without its benefits. It not only revealed the necessity of a reform in our monetary system, a lesson as yet blindly unheeded by the nation, but taught as well the need of industrial economies, and along this line most commendable progress has been made. During the past three years every manufacturer's office has been a school room, whose instructor has been Necessity, and the lesson that of applied economies and cheaper production. Mr. Carnegie, for instance, was an apt student and learned the lesson quickly. He built a railroad from the south shore of Lake Erie to his furnaces on the Monongahela and cut the rail carrying charge in two. He went beyond that. Availing himself of the dilemma of Mr. Rockefeller, possessed accidentally of several large deposits of ore on the south shore of Lake Superior, he was able to place himself in a position as regards ore supply to compete with the world, at the same time lowering the transit cost of the ore from the mine to his railroad. Mr. Rockefeller in turn saw meager profits, unless, availing himself of the deeper channels furnished in recent years by the government, he had larger boats to carry his ores than have been running in the trade. He built a dozen of them, and thus it happened that more than half of all the steel tonnage in the merchant marine of the United States built in 1896 was the product of our lake shipyards, and surely our pride in that we now own more than half of the merchant marine of the United States, as regards boats of 1,000 tons burden and over, is quite pardonable.

Everywhere, less noticeable because on a lesser scale, the same trend toward the same end is to be found. It has not received the attention it deserves—the constant, determined, intelligent effort of the American manufacturer, during the years of financial trial, to open new markets, stop wasteful expenditures, cheapen production. With returning prosperity he is rash who will set limitations on American trade abroad or at home—a result of the discipline of 1893-94-95. The growth of our export trade in the iron list is unmistakably genuine, recognized and frankly acknowledged by English competitors. The Duke of Devonshire, at the meeting of the Barrow Company directors, spoke of it as "alarming." The London Times, commenting on his declaration, marvels at the magnificent scale of operations at Homestead, where it finds furnaces each producing 200,000 tons of pig iron per annum, the average capacity of the English furnaces being less than 24,000 tons per annum. During the last month or two rails for Liverpool have been coming to tide water all rail from the Cleveland district. Nails and wire rods have been going abroad in generous quantities. The future is full of hope, if unwise legislation does not create more artificial barriers than the ingenuity of the American manufacturer can overcome.

Contributing to this happy condition of affairs, the cheap transportation on the lakes has been a factor of prime importance. The transporting interests on the inland waters have not failed to meet the new situation with intelligent effort and splendid courage. It was inevitable that cheaper transportation should come. The 20 foot channel from Duluth to Buffalo is practically completed, and the invitation to larger boats and cheaper rates could not be denied. Besides, the traffic itself is of such magnitude as to compel a minimum rate. Over that course of commerce must come the nation's breadstuffs, its lumber, its iron ores and copper in quantities that pass comprehension. The figures for 1897 are, of course, not yet complete, but there is little doubt, if any, that the most prosperous year will be equaled, even surpassed. If this proves true, over 28,000,000 tons of freight will have passed through the Detroit River in 1897. Load that freight in cars, 20 tons to the car, place the locomotive at New York, and the caboose will be in New York as well, but between the two nearly 2,000,000 cars will be found, extending across the continent to San Francisco, back again to New York, again across the continent, again back to New York. It is a greater commerce than that of Liverpool or London, foreign and coastwise, greater than both combined. It exceeds the total entries and clearances in the foreign trade at New York, exceeds the total of like entries and clearances at all the seaports of the United States. I am speaking of quantities, of course, not values.

Imagine, if you can, the uses to which the freight is put, the industries it nourishes. Sixty-six per cent. of all the ores used in the United States comes through the Sault, and, notwithstanding the bright outlook and flattering showing made by the Alabama and Tennessee district, the percentage of the total amount of ores used is not only markedly in favor of the Superior ores, but the percentage increases year by year.

Two-thirds, then, of all the ores used in this country come from the south shore of Lake Superior, and are the sole source of supply of such mills as those of the Carnegie Company, the Illinois Steel Company, the Johnson Company, the Cleveland Rolling Mill Company and others that are now confessedly equipped to compete for foreign trade. If our hope in the future supremacy of the American iron and steel maker is well grounded, surely we may look for its justification in the furnaces between Cleveland and Pittsburg. There, if anywhere, must be found the means by which in an iron age this country may assume a commanding position in the iron markets of the world.

And the whole matter depends on cheap transportation. Remove the chain of lakes, and no railroad or system of railroads could hope for a moment to place the 140 different iron and steel manufacturers in the Central States district in a position to compete with foreign mills, and in the catastrophe thousands of allied industries must inevitably be abandoned. For the coal for the coke is in western Pennsylvania and the ores over 900 miles away. No railroad in America is better equipped to transport freight cheaply than the Lake Shore and Michigan Southern. Its grades are light, its tracks and roadbed unsurpassed. The cost per ton mile in 1896 on that railroad was 3·81 mills; the cost on the lakes 0·89 mill. We have this year reduced the latter figure fully one-third in the operation of the larger boats. We have been bringing ore from the south shore of Lake Superior to Cleveland at a rate of but 15 cents per ton over the ordinary railroad switching charge in any of our large cities. We have been taking coal back at one-third the New York lighterage rate.

To reach such results has demanded the most rigid regard for economies in every direction. It has worked a revolution in loading and unloading cargoes. It became necessary that appliances should be such that 6,000 tons of ore could be loaded into a boat, the boat trimmed and ready to depart for her eastern terminus within four hours after tying up to the dock. It became necessary that at this end of the line those 6,000 tons should be unloaded in ten hours. It became necessary that 40 cars an hour, each car containing 25 tons of coal, should be lifted up bodily one at a time, and the contents discharged into the boat as easily as a laborer flips his shovel.

When Mr. Carnegie amazed the world last spring with his low quotations and other mills followed, let it not be forgotten that it had been impossible but for our shipyards, the genius of the mechanical engineer, and our steamship organizations, which have availed themselves of every known appliance for the economical conduct of their business. Had it not been for them and the lakes, Mr. Carnegie had sought in vain for his foreign market, Mr. Moxham had returned from Liverpool empty handed, and the Cleveland rod and nail mills had never dreamed of Japan and England for profitable sales. The commercial supremacy of America in iron and steel manufacture is impossible but for the great lakes.

And now let it not be thought that the greater part of that traffic is the carrying of iron ores. It is nearly a half of the tonnage, it is true, but in value occupies but fourth position. The total value of freight passing through St. Mary's Falls canals in 1896 was over $195,000,000. Of this amount wheat must be credited over $47,000,000; flour, $34,000,000; unclassified freight, $31,000,000. Iron ore with $25,000,000 comes next, closely pushed by copper with $23,000,000 to its credit. If the grain shipments out of Chicago and the lumber shipments from Lake Huron be added, and again there be added the value of the coal and merchandise shipments from Lake Erie to Detroit and Lake Michigan ports, the importance of iron ore in the list is not so readily recognized, and it will be seen that what I have said of the lakes and their relation to the iron industry ap-

* Read at the New York meeting of the Society of Naval Architects and Marine Engineers.

plies quite as well to wheat, corn, oats, flour and possibly copper.

It is almost certain that the indirect effects of lake transportation are of greater importance than the direct. Mr. Blanchard, in his argument of March, 1894, before the Committee of the United States Senate on Interstate Commerce, made a significant and, as I believe, absolutely truthful statement in these words: "I contend," he said, "that after rivers, lakes, oceans and economic forces have spent their combined natural and national powers in determining rates which are reasonable, such rates cannot be made excessive by combination." Mr. Blanchard was defending railroad pools, a question alive to-day and destined to command careful public consideration in the years to come. As a representative of the railroad interests his plea may be that of an advocate, yet the fact is he was entirely correct. No railroad or combination of railroads can dissociate itself from the traffic means we are considering. It is a controlling factor, and if Duluth can ship her flour from that port to Liverpool for 14½ cents per hundred—a privilege she enjoyed for a brief time the past summer—its effect is instant upon every railroad that has flour mills to protect or grain to haul to them. And then, too, it is not iron ore, flour and wheat that alone monopolize the low rate. The class freight annually carried over the lakes between the great commercial centers, Chicago, Milwaukee, Detroit, Toledo, Cleveland and Buffalo, and beyond in connection with the rail lines and the Erie Canal, is an item concerning which, unfortunately, no accurate data are at hand, thanks to a law which does not exact reports of any considerable statistical value; but the fact that all your trunk lines whose western terminus is Buffalo own and operate their own boats, and the fact before cited that the unclassified freight in the Lake Superior trade amounts in value to over $30,000,000 per year, hint at the enormous value of the total class business transacted in the lake trade. None of the trunk lines may ignore it and its influence is far felt. If it became a traffic necessity for the Lake Shore & Michigan Central and the New York Central & Hudson River Railroads to approximate the lake and rail or lake and canal rate on any commodity from Chicago to New York, be sure the other trunk lines will meet it, and give their tide water terminals the same rate, not omitting the differentials. As was the case this summer, even the north and south lines, such as the Illinois Central, must of necessity take a hand, protecting their Gulf termini against the competition thus forced on them. Now, while its effects are of little consequence, perhaps in regard to higher class freight, there can be no question but all the 6,000 railroad stations east of the Mississippi and north of the Ohio River reap a decided benefit in the carrying cost of the lower class freight and commodities; for when through rail rates are reduced between Chicago and New York for instance, because of lake competition, they are simultaneously reduced between intermediate points because of the long and short haul clause of the interstate commerce act. The effect is widespread, often disastrous to the carrier, but at least yields this comfort: That the present unmistakable tendency toward concentration of railroad interests or the enactment by Congress of a law permitting railroads to pool is a menace of academic rather than real interest. So long as our water highways are open, the railroads have a competition that cannot be overcome.

There is another reason why this competition is irresistible. In the building of boats and their machinery, the naval architect and marine engineer may hope reasonably to keep in advance of the maintenance of way engineer, the master car builder and the superintendent of motive power. Walking through the Globe shipyards one day with Mr. Parkhurst, he picked up a piece of coal the size of a walnut and remarked: "You would hardly think that little lump of coal will carry a ton of freight a mile, would you? and yet that is what it will do on our better class of boats." It is true—fifty-five hundredths of an ounce of coal per ton mile is the record.

Now, such results are not to be expected in the performance of a locomotive; at least they are not in sight. Such economies are associated with triple and quadruple expansion engines, and it is worthy of note that, for the first time in the history of shipbuilding in America, we on the lakes are now building our freighters with quadruple expansion engines. Then, too, our waterways are being deepened, our boats enlarged. Until last year they were less than 400 ft. long. We are now building them 475 and 500 ft. in length over all.

There is in a workshop at Cleveland an internal combustion engine, built for the company with which I am associated. It weighs about two tons, and is, if I mistake not, the first compound gas engine that successfully meets all requirements. Its cards show an indicated horse power of 111 and a thermal efficiency of 39·5. Making no claim whatever to a technical mechanical training, I am perhaps treading on dangerous ground, but this at least is known: That reduced to steel strains we have an engine of 92 horse power per ton, a record far surpassing that of the Turbinia, an engine that exhausts at atmosphere and that may be built to any power if some of your own brightest marine engineers are not in error. In any event, it is certain the principle of a compound gas or oil engine is now thoroughly understood, and whether the present device fulfills expectations or not, assuredly the time is not far distant when important results will come from the untiring efforts of mechanical engineers to transfer the source of power from the boiler to the cylinder. I mention it because indicative of a possible revolution in mechanics that will work economies in the engine room of a vessel impossible to the locomotive, and thus increase the already marked difference between the cost per ton mile by water and that by rail.

Clearly we have not yet sounded the possibilities of cheap transportation by water, and with their discovery one may be justified in believing that their application can nowhere be productive of more beneficent results to mankind than on those waters to which are annually consigned the products of the vast plains of the West, the nation's food and the supply of her workers in iron.

London has 196 inhabitants for each square kilometer, Paris 365, Rome 290, Turin 340, Naples 169, and in her Pendino quarter 1,254.

A GALLANT REGIMENT.

THE storming of the heights of Chagru Kotal has been justly described as one of the most stirring feats of war in Indian army annals. The story of the fight reminds one of "The Drums of the Fore and Aft," for it was the Highlanders and the Gurkhas who saved the day. The Gurkhas, it will be remembered, led the attack, and succeeded in getting into shelter inside the line of fire of the tribesmen, who were strongly posted on the hills. Next came the Derbyshire and Dorsetshire regiments, but the hail of bullets made them fall back. Then Col. Mathias called on his Gordon Highlanders. "Men of the Gordon Highlanders," he said, "the general says that the position must be taken at all costs. The Gordon Highlanders will take it." With the bagpipes rousing echoes in the hills, the men leaped to the attack and carried the positions in superb style. During this splendid rush Lance Corporal Piper Patrick Milne was shot through both legs, and he was brought helpless and bleeding to the ground, exposed to the deadly fire of the enemy as he lay in the bullet-swept zone. Milne, if not quite the first to leap into the zone, was among the first party of Highlanders. As he ran, he piped lustily the "Cock of the North." When shot down he managed to get himself into a sitting position, and with gradually diminishing vigor continued to play. But he was only one of five Gordon pipers who won praise by their pluck at Chagru Kotal. The other four sturdily marched across the zone fire, piping all the way. Only one got across unhurt. Three of them were wounded, one of them severely. Lance Corporal Piper Patrick Milne is an Aberdeenshire man hailing from Insch, where his

LANCE CORPORAL PIPER PATRICK MILNE.

father was a farmer. At the age of nineteen he enlisted at Aberdeen Barracks, and sailed for India in 1893. When he had been two or three months in India, Milne received his first good conduct badge. While at Sabatha he joined the pipe band of the regiment. He was with the Gordons through the Chitral campaign, and had then a wonderful escape. While playing his pipes a bullet struck the pipe bag within an inch of his side, rendering the pipes useless, but doing him no injury.

The First Battalion of the Gordon Highlanders, the old Seventy-fifth, was raised in the Highlands in the year 1787, but the Highland dress and title were discontinued in 1809, as there were not more than about a hundred Highlanders in the regiment. In 1862 it was given the title of Stirlingshire. Afterward it was linked with the Thirty-ninth Regiment. In 1881, on the introduction of the territorial system, the regiment reverted to its original position as a Highland corps, and became the First Battalion of the Gordon Highlanders. The First Battalion of the Gordons as a new Highland regiment soon won the respect and admiration of the rest of the Highland Brigade. At Tel-el Kebir the First Gordons did splendid service, and for their conduct at Teb and Tamai they were highly praised in Sir Gerald Graham's dispatches.

A detachment of the regiment fought at Abu Klea and Gubat. In 1885 the regiment was again on the Nile, but had all the unpleasant work of campaigning and none of the fighting. Last year it took part in the Chitral campaign, being present at the taking of the Malakand Pass. Thus, since 1882, the First Gordons has taken part in four campaigns, assisted in six pitched battles, and is now engaged in a fifth campaign. We are indebted for our cut and particulars to the London Graphic.

SELECTED FORMULÆ.

A peculiar fabric, which may find employment for many purposes, is made in Brussels. It is flexible, transparent and impervious to water. This textile material can be washed off with cold water, like a glass pane, by means of a sponge, and is mainly to be used for portières, window shades, umbrellas, etc. The patented process for the production of this tissue consists in filling up the meshes of a wide-meshed fabric, such as muslin, etc., with chrome gelatine or with a similar material, and then rendering the chrome gelatine insoluble by exposure to light. The fabric is then coated on both sides with boiled linseed oil or fat varnish. The treatment with chrome gelatine and linseed oil is repeated several times, and the fabric is ornamented by printing.

Spontaneous Combustion of Resinified Minium.—According to Prakt. Maschin. Konstr., resinified minium is subject to spontaneous combustion, as was proved by a fire caused by minium at a factory the other day. The hardened contents of a barrel of minium was broken up for the purpose of regenerating, and covered with bags overnight. The action of the oxygen of the air upon the fresh fractures of the hardened minium caused a development of heat in the same, under reduction to lead and ignition of the admixed varnish resins. Only by the vigilance of the factory watchman, a large accident was narrowly averted.

Red Ink.—

(1)	Carmine, No. 40	30 grains.
	Ammonia water	1 drachm.
	Acacia	6 grains.
	Water, q. s. to	1 ounce.

Dissolve the carmine in the ammonia, and add the other ingredients. The depth of tint may be varied by the use of more or less water.

(2) Half a drachm of powdered drop lake and 18 grains powdered gum arabic, dissolved in 3 ounces ammonia water, makes one of the finest of carmine inks.

White Ink.—White ink is made by suspending some insoluble substance in a liquid and applying with a brush or pen. In this way zinc oxide (Chinese white) may be ground very fine on a slab with a little mucilage of tragacanth, then thinned to the required consistency to flow from a pen. The mixture requires shaking from time to time to keep the pigment from separating. The ink may be preserved by adding a little oil of cloves, carbolic acid, or other antiseptic to prevent decomposition. All so-called white inks for colored papers are made from acids or alkalies which will discharge the color. The following preparation is used for writing on slate colored, blue or red paper:

Slaked lime	4 drachms.
Tragacanth, in powder	16 grains.
Glycerine, a sufficiency.	
Distilled water	4 ounces.

The lime is rubbed with the tragacanth and enough glycerine to make a stiff paste; rub for about fifteen minutes, and then add the water, and bottle.

The following is an ink for a blue paper:

Hydrochloric acid	1 fluid drachm.
Mucilage	30 minims.
Water	7 fluid drachms.

—Pharmaceutical Era.

Liquid for Gold Paint.—Stir the fine metallic powder into copal varnish previously thinned down to the proper consistency with turpentine. (2) Brannt gives the following: Melt dammar with an alkaline carbonate and expose the melted, finely powdered mass for several months to a temperature of about 122 deg. F. The alkaline resin thus obtained is dissolved in a hydrocarbon below 302 deg. F. Any acid contained in the hydrocarbon is previously neutralized by the introduction of dry ammonia gas. The mixture of this lacquer with the bronze powder keeps for a long time. (3) Pour over 100 parts of dammar and a few pieces of glass in a bottle 900 parts of benzine. Pour off the solution from the fine sediment and glass, and suspend in it 300 to 400 parts of bronze powder. Fill in small bottles. A gold paint or varnish may be made as follows: (1) Digest shellac, 16 parts; gum sandarac, mastic, of each 3 parts; gum gamboge, 2 parts, all bruised, with alcohol, 144 parts. (2) Artificial alizarine or garancine is to be digested in a glass vessel in three times its weight of alcohol for twelve hours, and pressed and filtered. A solution of clear orange-colored shellac in alcohol is next filtered and evaporated until it has the consistency of sirup. The latter is now covered with a layer of tincture of garancine, which permeates it. The slight brownish tinge of this varnish—a tinge absent from gold—may be corrected by a tincture of saffron. (3) Pulverize 1 drachm of saffron and ½ drachm of dragon's blood, and put them into 1 pint of 90 per cent. alcohol; add 2 ounces of gum shellac and 2 drachms of socotrine aloes, dissolve the whole by gentle heat. Yellow painted work varnished with this mixture will appear almost equal to gold.—Pharmaceutical Era.

Old Corks can be cleaned by washing with water containing 10 per cent. of hydrochloric acid, then immersing in a solution of sodium hyposulphite and hydrochloric acid. Finally the corks are washed with a solution of soda and pure water, says the Pharmaceutical Era. Corks containing oil or fat cannot be cleaned by this method.

Manure for Flowers.—For hastening the growth of flowers the following fertilizer is recommended. It consists of:

Potassium nitrate	30 parts.
Potassium phosphate	25 "
Ammonium sulphate	10 "
Ammonium nitrate	35 "

Remedy for Locusts.—We give from Revue Scientifique a remedy against locusts, which has proved efficient in Natal: Dissolve equal parts of caustic soda and arsenic in thirty-two times their combined bulk of boiling water. Of this stock solution take one gallon, dilute it up to forty gallons, add ten pounds of brown sugar or sirup. In this solution soak straw or Indian corn stems, etc., and spread on the fields. The locusts, attracted by the sugar, eat the poisoned stems and die, others come and eat the dead locusts and are also killed.

ENGINEERING NOTES.

A diver in the Clyde recently worked for forty minutes at a depth of 186 feet, which is a record in Great Britain.

It is learned that the mammoth pontoon dock which is being built to Spain's order at Stephenson's yard on the Tyne is destined for the Philippine Islands, and not for Havana, as was at first reported. This dock is similar in size and construction to the one recently built and dispatched in tow for Havana.

A cable line has recently been completed connecting Puerto Cavello, Venezuela, with La Guayra, and thus with New York, by way of Curacao, Haiti, etc. A delay of many hours is avoided in the transmission of telegrams which formerly went over the national overland lines.

Consul Duester, at Crefeld, Germany, reports to the State Department a discovery made there which, it is said, will revolutionize the methods of illumination. It is an incandescent gas. A single jet of ordinary size can emit a light of much more than 1,000 candle power, and fine print can be read at a distance of 100 feet. The inventor says the cost for a light of 1,500 candle power is only $4\frac{1}{8}$ cents per hour, while that for an ordinary electric light of 400 candle power is 14 cents per hour.

It is announced that the steamers of the Peninsular and Oriental Company will, after February 1, 1898, call at Marseilles instead of at Brindisi, owing to the niggardly policy of the authorities at the latter port in refusing to extend the local railroad half a mile to the quay for the accommodation of passengers and mails. This action upon the part of the officials of Brindisi makes them responsible for the loss of business involved in the landing there of 110 large passenger ships yearly.

We are informed that, for safety's sake, the receivers of the Baltimore & Ohio Railway have placed out of service nearly all of the old iron hopper cars which have been used on the Baltimore & Ohio for a great number of years. These cars, it is stated, were very weakly constructed, and if put in a train between the heavy modern freight and coal cars of to-day, are very likely to be crushed in case of a sudden stop, or a too strong application of air brakes. Up to September 30, 1,500 of these hoppers had been retired and thrown on the scrap pile.

The use of aluminum bronze is increasing for purposes where a strong and dense metal is required, says The Aluminum World. The amount of aluminum in aluminum bronze varies from a few per cent. up to 10 or 11 per cent., depending on the purpose for which the metal is intended. The strongest mixture contains between 10 and 11 per cent. of aluminum. Beyond this point the bronze is hard to work and becomes brittle. Aluminum bronze can readily be soldered. In soldering this alloy no such difficulty is encountered as is found in soldering pure aluminum. The best method of soldering aluminum bronze is to use pure block tin with a flux made from zinc filings and muriatic acid. It is well to "tin" the two surfaces before putting them together.

According to an article on the "Comparative Fusibility of Foundry Metals," in The American Manufacturer, the economy and advantages to be obtained by using chilled pig metal in foundries and in Bessemer steel works are as follows: First, being a harder iron by reason of its chill, or having its carbon largely in the combined form, as well as having the pigs free of sand, less fuel will be needed to melt it, and it can be made to come down faster in the cupola, thus saving time in melting. Second, the pigs being sandless, there will be needed less fluxing and slagging of a cupola in large heats, and this will also give a cleaner iron out of small as well as large heats from the tap hole. Third, its being chilled will cause it to be broken more easily. Fourth, the general use of chilled cast pig metal would do more to compel the use of chemistry in founding, because those who still make mixtures of iron by judging grades by fracture would be forced to work by analysis, as chilling a pig would more than ever disguise its chemical composition.

The rapid extension of the iron industry in European Russia, through the establishment of the several large new iron and steel rolling mills already erected, or now in course of erection in the country, has called into existence a new branch of the iron business which hitherto depended chiefly on foreign supply, says The Engineer, the construction of plants for the manufacture of iron and steel. New works for this purpose have just been opened in Riga by a company forming a branch of a similar one in Dahlbruch, in Westphalia. The Riga company has secured a well situated piece of ground of $17\frac{1}{2}$ acres, so as to be able to extend its works to fourfold their present dimensions. The buildings and machinery, including a 30 ton crane, are all of the most improved description, and are provided with electric transmission of power and electric lighting. The designs for the machinery to be constructed will be furnished by the parent establishment in Dahlbruch. Germans, Belgians and Frenchmen are taking a firm hold on the iron production business in Russia.

Since the institution of cotton mills at Shanghai, the wheelbarrow has been extensively used as a passenger vehicle, especially for carrying workwomen to and from the mills. One man can wheel six women for a distance of about three miles, morning and evening, the charge being 35 cents per month. The average earnings of a wheelbarrow man are about $8\frac{1}{2}$d. per day. About 4,000 licenses are issued monthly to the same number of wheelbarrows plying for hire in the streets of the foreign settlements at Shanghai, where, being under the municipal regulations, they are perhaps the best in China. Sometimes as many as fifty barrows may be seen in the streets, traveling one behind the other, each carrying two barrels of English Portland cement and pushed by one man. Very frequently a load is carried on one side of the barrow only, and it is extraordinary to see a Chinaman skillfully balancing and propelling it. The upsets and accidents, too, according to [illegible]'s Magazine, are remarkably few, when it is cons[illegible] that about 4,000 of these vehicles are in use in the streets, in addition to a large traffic of other kinds.

ELECTRICAL NOTES.

Letter stamping machines are being experimented with on the trolley postal cars in San Francisco, the machines being run by motors that take current from the trolley circuits.

The street car system of Munich is to be wholly converted into an electric line system within the coming two years. The plant is to be three times as powerful as the one at Berlin, and is to supply electricity for lighting purposes and to private individuals, besides running the cars. Expenses are estimated at two and three-fourths million dollars.—Uhland's Wochenschrift.

Cutting Up Trolley Wires.—Not a month passes, says the Street Railway Review, of Chicago, but we record the loss of trolley or feeder wire which has been stripped from the hangers and is usually found chopped up into short lengths of a foot or two, suitable for melting into pigs to prevent identification. Some months there are several such reports, the losses ranging all the way from a few dollars to several hundred; and occasionally the damage done causes an expense of one or two thousand. The nuisance is not confined to any State, but is "prevalent all over."

From experiments recently made on specimens of iron of different lengths, Mr. Henry Wilde, F.R.S., has found the magnetization limit to be 422 lb. per square inch, or 29·67 kilos. per square centimeter. In his communication to the Royal Society, Mr. Wilde describes an experiment showing that the single pole method of determining the magnetization limit of magnetic substances compares favorably with the double pole method, and that no higher degree of tractive force is to be expected from the latter than has been obtained from the former method.

Under date of August 30, 1897, Consul Germain writes from Zurich: The total length of the world's telegraph system has now reached 7,900,000 kilometers (4,908,823 miles), exclusive of 292,000 kilometers (181,440 miles) of submarine cables. This mileage is apportioned as follows: Europe, 2,840,000 kilometers (1,764,790 miles); Asia, 500,000 kilometers (310,685 miles); Africa, 160,000 kilometers (99,419 miles); Australia, 350,000 kilometers (217,479 miles); America, 4,050,000 kilometers (2,516,548 miles). It will, therefore, be seen from the above that, notwithstanding the steady increase in the building of telegraph lines all over Europe, America leads and has almost double the mileage of Europe.

A novel method of illuminating the new Low library at Columbia University is being tried experimentally, says Electricity. The idea is to gain the advantage of diffusion from a large surface centrally located, and at the same time to be realistic. The plan being tried is as follows: Suspended in the center of the great hall is a large hollow globe seven feet in diameter and painted a dull white. This is not a receptacle of the light intended to diffuse the rays by transmission, but is opaque and intended to diffuse the rays by reflection. Upon this sphere are directed the concentrated beams of light from eight hidden arc lamps located at intervals along the gallery pilasters. The moonlight effect is heightened by the background of blue which constitutes the ceiling, and the effect is described as fine in the extreme.

Some rapid electric railway construction was recently accomplished near Bound Brook, N. J., where $2\frac{1}{4}$ miles of road was constructed in 22 hours, including all grading and overhead line construction, by the New York & Philadelphia Traction Company in an effort to outwit a rival company and prevent the stopping of work by an injunction. The right of way between Bound Brook and Somerville was being disputed by the New York & Philadelphia Company and the New Brunswick Traction Company. The former quietly arranged with J. G. White & Company, of New York, to build the section during the 24 hours between 12 o'clock Saturday and 12 o'clock Sunday nights, says Engineering News. The work required the transportation of 600 men, four cars of tools and provisions, large quantities of poles and ties, lighting apparatus, tents, etc. The work was accomplished, current turned on from a temporary power station built on the property of an interested party, and a car run over the line within the allotted time, notwithstanding the opposition of the local authorities, who were obliged to succumb to the superior numbers of their opponents.

An electrical transmission plant has recently been completed by the Blue Lake Water Company in Alpine and Amador Counties, California, says Engineering News. Ten small lakes between 4,000 and 8,000 ft. above the power station, with a catchment area of about 67 square miles, form the source of water supply. By damming their outlets, a total storage capacity of 20,912,000,000 gallons was secured. These lakes discharge into the Mokelumne River, and at a point about 45 miles from the lakes the water of this stream is diverted into the Amador Canal. This is an artificial channel $42\frac{1}{2}$ miles in length made through very rugged country. There is one tunnel and 82 flumes, aggregating 3·7 miles in length. The canal has a grade of about 8 ft. per mile, which gives a velocity of 300 ft. per minute and a capacity of 3,000 miner's inches. The ditch ends in a concrete forebay and settling basin, which also forms the upper end of the pipe line. This conveys the water a distance of 3,340 ft. to the turbines, with a drop to the point of delivery of 1,242 ft. The pipe is in five sections, which vary in diameter from 48 in. at the upper end to 15 in. at the turbines. Where flange joints were made, $\frac{1}{8}$ in. sheet lead gaskets were used as packing, and these were compressed by drawing up the flange bolts until only $\frac{1}{8}$ in. thick. In a test of sections of 15 in. pipe joined in this way, a pressure of 1,200 pounds per square inch was withstood. To anchor the pipe and prevent mechanical injury, the entire length was sunk to the surface of bed rock, and the last 400 ft. was embedded in concrete in a trench blasted out of the solid rock. Three 700 horse power Doble water-wheels 4 ft. in diameter, with a working speed of 600 revolutions per minute, are directly connected to three Stanley two-phase inductor generators. The power generators give 7,200 alternations per minute, with a voltage which can be regulated from 2,000 to 2,400. An interesting feature is the entire absence of any sort of receiver or air chamber. Notwithstanding the great pressure employed, nearly 560 pounds per square inch, the only protection at present against water hammer is a form of gate which cannot be closed rapidly.

MISCELLANEOUS NOTES.

Is a factory chimney real estate or is it part of the machinery? This question is now engaging the attention of the city assessors of Montreal, on the claim of the Montreal Street Railway Company that their chimney, now assessed as real estate, is really an important part of the mechanical plant, and as such is exempt from taxation. Of the $75,000 expended on the power house of the company fully one-third was used in erecting the chimney. On this point the assessors themselves differ, chimneys being assessed as real estate in some Montreal wards, while they are exempted in others.

The great salt wells at Tsz Liu-Ching, China, is the title of a recent consular report. In the region mentioned no less than 250,000 persons find employment in operating the 5,000 wells and necessary refining machinery. Most of the wells range from 2,000 to 3,000 ft. in depth. They seem to have been bored with a form of hammer drill supported at the end of bamboo ropes. The work of drilling progresses very slowly, in one case progressing only two inches per day, and a well requires many years to complete. The upper or earth section is usually lined with cedar tubing to keep out surface water. From many of the wells natural gas flows, often under considerable pressure. It is used as a fuel in evaporating off the brine. The brine is raised from the wells by a bucket and windlass, the latter operated by buffalo power.

The London Engineering says: "The French manufacturers of asbestos goods are supplied from four sources: 1. Canada, whence the asbestos is white, silky, very unctuous, having supple fibers from 5 to 25 millimeters in length; of all varieties it is that which spins the most easily. 2. Siberia, whence the mineral is yellowish, some species being of a straw yellow. The fiber is less flexible and more woody, but stronger than the Canadian, which it resembles in length; large masses of long fiber mineral being, however, rarer. 3. The Cape of Good Hope asbestos has a characteristic blue color. It occurs in larger masses than either the Canadian or Russian, and its fiber is generally longer and stronger. In spinning or other manipulation, however, it is difficult to handle, a good deal of the fiber being reduced to powder. 4. In Italy there are different kinds of asbestos, but generally they are little adapted to spinning. There are some long silky fibers of little resistance, employed for gas furnaces; others are very short and fit only to make heat-retaining coverings."

The best aluminum alloys have about 16 per cent. less strength and rigidity when drawn into tube than a steel tube of the same weight and outside diameter; but, owing to its much greater thickness, the aluminum tube can be made of larger diameter without danger of buckling, says Aluminum and Electrolysis. For bicycle handle bars aluminum has greater advantages, and if it could be readily plated it would be really valuable for this purpose. The difficulty of joining is much against it in most cases. For the comparison of strength and rigidity the tubes tested were both 1 in. outside diameter, and practically of the same weight per foot: the steel tube was 20 gage, or 0·036 in. thick, and the aluminum alloy 12 gage, or 0·110 in. thick. The superiority of the steel tube was due to its greater mean diameter. Making allowance for this, the strength and stiffness of the two materials are nearly equal. The maximum stress in the steel tube was 52 tons per square inch, and in the aluminum alloy, 18·7 tons per square inch. The effect of a brazen heat was to reduce the strength of the steel by 45 per cent., thus bringing down its maximum stress to 28·6 tons per square inch; the stiffness was unaffected.

Talc is extracted on a large scale from the granite mountain of St. Barthelemy, in the French Department of Arriège, about 32 kilometers (20 miles) from the main chain of the Pyrenees. The principal quarry at Trimoum is worked open cast in three banks or terraces, each about 15 meters (49 feet) high. The best rock is of a bright white tint, and feels greasy to the touch when reduced to fine powder. The quarried rock is brought by a tramway to the end of the quarry in the Axiat Valley, and then by wagons for a distance of 19 kilometers (11 miles) to Luzenac, where 90 H. water power is taken from the Arriège River. The mechanical preparation consists of drying in a rotary oven, breaking up small, grinding and sifting, the grinding being effected in mills with steel balls. The larger portion of the product, observes an Ingénieur des Arts et Manufactures, who has communicated these particulars to the Chronique Industrielle, is converted into powder, only a small portion being sent away in the rough state, or cut into pencils for writing on metals. Besides its use throughout most parts of Europe and America, in soap and paper making, talc enters into the composition of wagon axle grease, while it also serves as an insulator for electric conductors.

Consul Morris, of Ghent, under date of September 3, 1897, says: The common council of Courtrai, Belgium, has just voted the exemption from certain taxes for workingmen who build dwellings for their own use. The conditions in brief are: There shall be exempted from the building, paving and sewerage tax: (1) the workingman who, not being an owner of real estate, erects or transforms a building destined to be used by him as a dwelling, and who has secured the property in accordance with certain conditions accorded to workingmen; (2) all societies associated with the Savings Bureau of the Government which erect or transform buildings by one of the methods prescribed by the said bureau, thereby assisting workmen to the ownership of a dwelling house; (3) incorporated associations, organized for a period of at least ten years, which erect buildings destined to be rented to workingmen and which agree in their charter that their dividends shall not exceed 3 per cent. The taxes are payable: (1) if the workingman does not actually occupy this house within three months after it becomes inhabitable; (2) if, before the expiration of five years, he ceases to occupy it or transfers the property to another party not entitled to the exemption; (3) if he establishes in it the sale of liquors. The corporations mentioned must be chartered and must publish their by-laws. If they do not fulfill all details of law, they forfeit their rights to exemption. At Bruges, in 1890, the common council voted the abolition of these same taxes in favor of all properties the annual income of which was less than $27.80.

AUTOMATIC WEAPONS.

THE advantages and disadvantages of the repeating gun have been discussed by specialists for nearly twenty years. Although most armies have hesitated to introduce it, it is not for want of very practical systems, with magazine or loader, permitting of obtaining great rapidity in firing, but rather on account of this very rapidity, which many military men fear as the surest means of depriving them of ammunition before the end of an unimportant battle. According to most officers, the discipline of firing would, only with difficulty, reach such a degree of perfection that it would be possible, at will, to quicken or retard the speed of firing of a troop provided with repeating guns. To-day, either because confidence in the education of troops has increased, or because the great European nations have acted in the matter by simple spirit of imitation, the cause of the rapid fire gun has won.

From the repeating system (rapid in charging, but slow in discharging) one has passed almost everywhere to the gun with a loader into which all the cartridges, generally twelve in number, may be introduced in a few seconds.

There remains only one more step to be taken in order to obtain the possible maximum of firing speed, through the use of the automatic weapon. This latter will perhaps be assailed by means of the arguments that retarded the use of the repeating gun, but there is no doubt that it will triumph over them, for the same reasons. The whole question at present is to know what system will prevail.

Up to the present, two processes have been employed for the maneuver of automatic mitrailleuses. In one (the Maxim) the recoil of the barrel is used for actuating the mechanism, while in the other (recently adopted by the Hotchkiss establishment) it is an escape of gas that serves to effect the motion. This process is older in the portable gun, the one that we are about to describe, and the construction of which is due to the Brothers Clair, of Saint Etienne. Not much studied up to the present as a war gun, this weapon has, nevertheless, reached a high degree of perfection as a sporting piece. It will not call forth the objections urged not long ago against the rapid fire gun used in the army. In hunting, the inconvenience of finding one's self deprived of ammunition is minimum, and one will scarcely reach the end of his supply of cartridges unless he engages in a genuine massacre. At the most, a sportsman who alone is provided with the new gun will be looked upon with an evil eye by his companions, to whose detriment he will destroy the game.

Fig. 1 gives an idea of the mechanism of the Clair gun. Not far from the edge of the muzzle there is a lateral aperture that gives access to a cylindrical chamber closed by a piston. The latter is mounted upon a hollow rod fixed at the rear to a rod connected with the maneuvering handle of the breech mechanism. Upon the whole, this mechanism is quite similar to that of the Mannlicher gun, with simple motion from front to rear, without a revolving motion for cocking. The mechanism may be actuated by hand either for loading the weapon for the first time, or even during the course of firing; but, normally, it is the escape of gas in front that, acting upon the piston, furnishes the energy necessary for the maneuver.

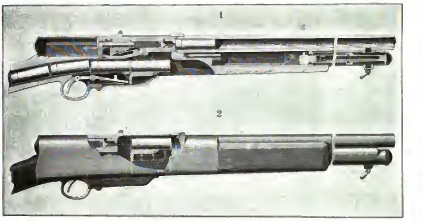


FIG. 1.—THE CLAIR AUTOMATICALLY LOADING GUN.

The piston, after its work is finished, is shoved forward by a spring; the breech closes, and the gun is ready for firing. This motion is extremely rapid. It requires close attention to follow it with the eye, and, in all cases, the gun is ready for firing before the sportsman has had time to raise the trigger and press it anew.

Fig. 3 is an exact reproduction of an instantaneous photograph taken during a firing with the Clair gun. Above the sportsman will be seen the empty shells, which have not had time to fall to the ground in the interval between shots.

If it happens that the sportsman does not wish to make use of the automatic reloading device, it will suffice to remove a screw plug, so as to allow the gas to escape to the exterior and no longer actuate the mechanism. It is almost useless to remark that the piston rod can act upon the breech mechanism only through a thrust, and that it is not carried along in the motion by the hand.

In the sporting gun, the cartridges are introduced one by one into the butt end through the loading aperture situated beneath the breech. The army gun, on the contrary, is provided with a loader.

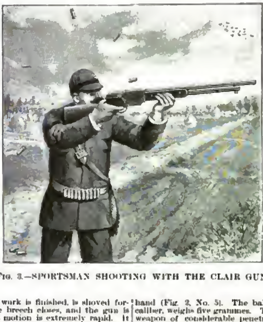

FIG. 3.—SPORTSMAN SHOOTING WITH THE CLAIR GUN.

The second weapon that we shall describe is a repeating pistol invented by M. Borchardt, and that appears to have been submitted to a series of experiments by the German military authorities. This pistol (Fig. 2) is of the type known in France as the mitrailleuse. Like the Maxim gun, the Borchardt pistol operates through the recoil of the barrel, which slides in two grooves that serve as a guide, and shoves backward, by an abrupt motion, a jointed rod of which the pivoting point is situated in the posterior appendage of the weapon.

For the position of the handle, a return has been made to an old form once used in certain fancy weapons. The body of the pistol rests upon this through its center of gravity, thus giving the hand a minimum of effort in firing with extended arm. Such position of the handle, moreover, was indicated by its function. It serves, in fact, as a sheath for the loader, which contains eight cartridges, and which may be replaced instantaneously, when exhausted, by another and full one. This arrangement, furthermore, permits of utilizing the entire length of the weapon for the line of aiming—a very important condition for accuracy in firing. As with the gun above described, the automatic loading may be replaced by a maneuver by hand (Fig. 2, No. 5). The ball, which is of 7·7 mm. caliber, weighs five grammes. This pistol is a very fine weapon of considerable penetration and great accuracy, and is very usefully completed, especially for war purposes, by arrangements that assure ease of carriage and increase the accuracy of its firing. For a march, it is strapped to a piece of wood in the form of the butt end of a gun, and is inclosed in a leather case to protect it against rain and dust. When it is to be employed, it is unstrapped and used as an ordinary revolver, or affixed to the butt end and used for shoulder firing.

We complete our description in saying that the weapon, suspended on the right side by a shoulder strap, for marching, can be affixed to the butt end in the vicinity of the enemy, so as to be made instantaneously ready for firing.

This new pistol is not only interesting by its ingenious mechanism, its exceptional ballistic qualities, its rapid fire and ease of carriage, for it may be said without any exaggeration that it prepares the way for an evolution in the armament of mounted troops, of artillery of all categories, of military bicyclists, and, in a general way, of all bodies of soldiery whose firing is done only at short or medium distances, and by whom portable firearms are used only exceptionally and to whom they should never prove cumbersome.—La Nature.

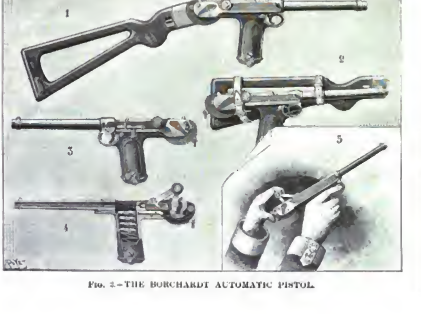

FIG. 2.—THE BORCHARDT AUTOMATIC PISTOL.

The results of some paint tests were exhibited at the October meeting of the Civil Engineers' Society of St. Paul, says the Railway Master Mechanic. Twenty-odd samples were shown of black and more or less rust roughened plates of sheet iron which had undergone six months' exposure to locomotive smoke while suspended from the roof of the Union Depot train shed about 50 feet above the tracks. The iron plates, originally new and bright, had each received one coat of paint and had been subjected to equal exposure. The red lead samples gave the best results, next came the white lead, followed by the iron oxides and the asphaltum, which were generally in much better condition than the graphites. An anti-rust specimen was the brownest specimen of the lot.

ELECTRIC TOWAGE ON CANALS.

THE towboats that we have described in a previous article are especially adapted for hauling barges over natural channels. To secure the most economical results, the traction ought to be supplied to the convoys as continuously as possible. This favorable condition is found on rivers either in their natural state or regulated, and usually only interrupted by locks of large dimensions and at long distances apart. But the conditions are very different for the most part on canals, where locks are generally numerous, and not large enough to receive a convoy; the length of the reaches is also, as a rule, very unequal, and under these conditions the haulage of long tows becomes impracticable. Where it is necessary to lock the boats one by one, it is evident that the difficulties of economical haulage in groups become excessive, and for this reason the use of horses has been hitherto found most advantageous, in spite of the numerous experiments in mechanical traction that have been made. The chief obstacle has arisen from the necessity of dividing among a large number of barges the small and independent units of power necessary for each.

The first cost of any such installation must unavoidably be large; and in order to compete with the cheaper horse traction, the expenses of working must be very low. For this reason those systems of mechanical haulage that require the employment of an additional man on each boat involve additional cost, and thus render them inapplicable. Towing by light locomotives running on rails laid upon the canal bank possesses many well-defined advantages, but is attended with other difficulties besides that of excessive cost. It is not a part of the scheme of these articles to consider the relative advantages and drawbacks of the various methods of mechanical haulage on canals; and we refer to them simply as an introduction to a method which has recently been tested on the St. Denis Canal, and which is a modification of the Bovet system, that we have described.

About forty years ago a M. Bouquier suggested a solution to the problem of mechanical traction for canal boats. He proposed to place on board each barge an apparatus consisting of a portable engine driving a paddle wheel by a belt; this wheel was mounted so as to project from one side of the boat. Arrangement was made by which the whole device could be easily shifted from one boat to another, so that a maximum of work could be obtained with one plant. Numerous trials of this system were made, but it was ultimately unsuccessful, on account of the difficulty of transshipping the motor, and the cost of working. M. Bovet has, however, under widely different conditions, followed the lines of Bouquier, substituting an electrical for a mechanical motor. By this arrangement he has reduced the weight of the apparatus to about a ton, which does not appreciably reduce the carrying capacity of the boat. In the arrangement adopted no projection from the boat affects its width, so that the barges can be built as wide as the dimensions of the locks permit; this is an important detail, as it affects the prices charged for carrying freight.

The management of the electric motor is so simple that it can be intrusted to one of the boat's crew, so that no additional charge for wages is incurred. It is evident that electricity is better adapted than any other force for subdivision to actuate small powers, and a part of the current can be utilized for magnetizing the two pulleys. Figs. 1 to 5 indicate the way in which the plan has been experimentally tried on the St. Denis Canal. The barge employed carries about 300 tons, and is of the standard type used on the canals in the north of France. It is an unsightly structure, and offers a maximum resistance to towage. On the other hand, it is cheap to construct and contains the greatest room for stowage; the type is, in fact, one that has been evolved by experience. The towage gear and its motor are inclosed in a sheet iron box, and placed on the forward part of the boat, on a tripod frame, each leg being held by screws to the floor of the barge. The box is free to slide inboard on the frame in passing through locks. The current is brought to the motor from a cable carried on posts along the canal bank, there being a trolley running on the cable. From the trolley passes a flexible cable that extends to a mast on the barge; this cable is led over a pulley, and down the mast, and thence to the towing gear. At the bottom of the mast the cable is wound over a compensating drum, which always preserves a sufficient margin of cable to compensate for deviations in the course; the drum is controlled by a spring that winds up any slack that may have been drawn off.

This means of regulation is necessary, as the mast has usually to be removed in going under bridges, and the cable has to be raised when passing other boats. It has been proved that this arrangement is much more satisfactory than a permanent trolley; not only because it must be placed high enough to clear obstacles met, such as masts, funnels, etc., but also because the trolley cannot be kept to a line over the boat, nor even on one side, as on many of the Brussels tramways, on account of the irregularities in width of water, formation

FIG. 1.

ELECTRIC TOWAGE ON CANALS.

of banks, etc. It has not been found practicable to make use of the submerged chain for the return circuit; the resistance is too great. This was clearly proved by the earlier experiments, and it was found necessary that there should be a return cable, and consequently that two trolleys must be used. Those that were first used, and answered well, were made with two deep grooved wheels on a counterweight; one of these trolleys was drawn by the cable and hauled the other. Of course there are various ways of making such trolleys, dependent on the special conditions. One satisfactory form is shown in Fig. 5. It consists of one trolley running on the lower line, and carrying a smaller trolley bearing on the upper cable, either by means of a lever and counterweight or by a spring. This trolley is not liable to derailment, and the man in charge of the boat has only one trolley, instead of two, to look after. The upper trolley can be easily shifted and the boat stopped, or if the way has to be cleared, the whole device can be brought inboard by means of a boat hook.

The tow gear that has been used consists of an electromotor running at 1,000 revolutions, and driving an intermediate shaft by contact between a cast iron fly wheel and a magnetized friction roller; from this countershaft the transmission to the tow pulley is by gearing. The diameter of the tow pulley at the bottom of the groove is 0·40 meter, and the normal speed at which it is driven is 40 revolutions, corresponding to 3 kilometers an hour. As in the Rue Royale sewer installation, already described, the chain rising from the water is guided by a heavy roller, the chain being assisted to leave the magnetized pulley by means of an insulated, or non-magnetic, metal lever. This lever and the guide roller are mounted on an eccentric wheel controlled by an endless screw to regulate the angle of winding round the tow pulley; this can be as much as 270°, or reduced to nothing when it is desired to throw off the chain. Figs. 4 and 6 illustrate the installation very clearly; the latter is an enlarged view of the towing device and the former a general view of the barge fully equipped. It should be mentioned that the wooden shelter shown on the barge was erected to protect the measuring instruments used during the experiments, and does not form any part of the installation. The barge with a load of 300 tons was hauled at a speed of from 2·8 to 3·8 kilometers per hour, with a current of 20 amperes and 110 volts at the station. At starting the current rose to 60 amperes, and then fell gradually, the normal rate being reached when the boat had traversed 80 meters. No difficulty was experienced with steering, in spite of the fact that the tow gear was on one side of the boat, and the trolleys gave no trouble. The conducting cables were needlessly heavy, being adapted for a current of 110 volts; they would have been, of course, much lighter for a 500 volt current. The experimental apparatus we have described and illustrated would be considerably modified for regular service.

The several applications of the Bovet system which are described prove the possibility of utilizing magnetic attraction for the development of considerable efforts; and it may be readily seen that the useful variations of this method may be numerous. In the course of the investigations he has made while pursuing the question of electric towage, M. de Bovet has been led aside in certain important deviations, especially with regard to transmission of power, and magnetic brakes; these have been very fully described in the Transactions of the Société Internationale des Electriciens, of Paris.—Engineering.

RADIUS OF ACTION OF ELECTRIC MOTOR CARRIAGES.*

THE objection that is most frequently raised against the electric motor carriage is "the difficulty of getting it charged." It has come to be the general conclusion among people even well versed in motor vehicle matters that a carriage propelled by electric storage batteries is unable to run beyond a very limited distance from an electric light station. In numerous instances even some of the technical journals devoted to the motor vehicle industry have carefully excluded the electric storage battery from the list of possibly successful motive systems.

So persistent have been these contentions that even in the minds of those who have had actual experience with well equipped electric motor carriages this question became one of doubt. In no recorded case had any one made an actual trial in a properly constructed electric carriage with a view to definitely ascertaining just where the touring limits of the electric carriage actually lay. It has been the good fortune of the writer recently to make an actual test of this question in one of the Pope Manufacturing Company's Columbia carriages. Although the makers expressly declare the vehicles to be designed for city and suburban service, and do not regard them as adapted to touring purposes, these carriages are fitted with the latest achievements in electrical traction apparatus, and the opportunity for the procuring of valuable information was an exceptional one. The experience, according to the best knowledge of the writer, is the first that has been recorded in which a carriage propelled by an electric storage battery was used for the purpose described.

The start was made from Hartford, Conn., one evening, with the intention of running through to Springfield, Mass., returning the next morning. Stops were to be made at as many towns along the route as was possible, in order to ascertain by experience what might be the actual difficulties, if any, of getting current for charging the storage batteries.

As the Columbia carriages are geared to a fixed speed of twelve miles per hour on a level, no consideration could, of course, be given to the question of speed, although the times of running were noted.

The first town out of Hartford was Windsor. The distance from the starting point was eight miles and the time occupied in making the distance was thirty-five minutes. The roads were in good condition, but quite hilly. The battery indicating meter indicated that $1\frac{1}{8}$ kilowatt hours of the total of 5 in the batteries had been used.

Upon arriving at Windsor information was asked as to the possibilities of getting electric current for charging the storage batteries. The information received was that the only place available was the works of the Eddy Electric Company, which were closed during the night. We were informed, however, that during the day time current was available at this place.

The journey northward was then continued, the next town being Windsor Locks. The distance from the starting point in Hartford to this place was thirteen miles, and the time occupied in getting there was one hour and fifteen minutes. Part of the road was through very deep and soft sand and numerous bad hills had to be ascended. Upon arriving in Windsor Locks inquiry was again quietly made as to the possibility of obtaining current for charging the storage batteries. We were promptly referred to the Windsor Locks electric light station. This place was found located at the foot of a short hill, the grade of which must have been 15 per cent.

Upon application at the station, it was found that the apparatus used for furnishing the town light was alternating, but that direct current was available from the exciting machines used in exciting the fields of the alternating current generators. The officials in charge of the station were most cordial, and in a very short time the necessary connections were made and the charging of the batteries in progress.

After permitting the charging to go on for about one-half hour, we considered the availability of current at this point adequately demonstrated. The wires were disconnected and we resumed the road northward after successfully navigating the 15 per cent. rise.

It had now become thoroughly dark, and the running through the quiet country in the cool, sweet scented air with the electric headlights of the carriage literally blazing was an experience inspiring to say the least. The almost noiseless action of the electric carriage and the perfection and simplicity of its control made the running seem ideal. Although the road throughout was entirely strange, it was found that the brilliancy of the electric headlights made traveling at night as safe as in the daylight. The road could be seen for at least 100 feet ahead, and the tinge of excitement when running into the dark, wooded districts added materially to the pleasure.

Thompsonville, on the east bank of the Connecticut River, which was crossed on the Enfield Bridge, was the next town reached. It is eight miles from Windsor Locks, and the time taken to make it was forty-two minutes. The roads were in very good condition and only one hill of any magnitude had to be ascended. Upon arriving, information was again asked as to the possibilities of obtaining electricity for charging the storage batteries, and we were at once directed to the Enfield Electric Light and Power Company. The carriage was run to this place, where it was found that Edison direct current apparatus was in use, which could be connected directly to the carriage terminals without any change whatsoever.

Although the people at this station had never before seen a motor carriage, the necessary connections were quickly made and in fifteen minutes the charging was in progress.

After remaining a short time the terminals were again disconnected and, after giving the officials at this station a sample ride about the town, the road for Springfield was again resumed. This road was found to be in excellent condition, but to have very many severe hills. All of the ascents of these hills, however, were made at a smart pace, thanks to the continued freshening the batteries had received, and it is needless to say that, owing to the now late hour, the descents were made at something more than a smart pace. In some places there is no doubt that the speed was fully 35 miles per hour. The road from Thompsonville to Springfield is through a fairly well settled country and is extremely pleasant riding. Springfield is about eight miles distant, and the time occupied in making it was forty-seven minutes. Arriving at Springfield, which has a large and unusually well equipped and regulated electric light station, we proceeded at once to the latter place. It was found here that alternating apparatus was the principal one used, and that, as at Windsor Locks, it was necessary to get the current from the exciting machines. Through the courtesy of the management, this was soon arranged, however, and the carriage was shortly being charged. At this place the battery indicator indicated three spaces of the five on the battery indicator as used. As it was desired to run about the city of Springfield in the morning before returning to Hartford, the batteries were charged until the indicating finger had returned completely to the "full" position. Having returned to this point, we departed for the Massasoit Hotel. Arriving here, we went through the ordinary procedure at the stable precisely as though we had an ordinary horse and carriage. Instructions were left with the stable keeper to wash the carriage in the morning, precisely as he would any other carriage.

In the morning, after breakfasting and listening to the interested talk of numerous people who had seen the carriage on the previous evening, we repaired to the stable and found everything in perfect condition. We then visited numerous places in the city, giving different people short rides, and at 9:30 we started on the return to Thompsonville.

Thanks to our generous dispensation of rides in Springfield, when about two miles out of Thompsonville the battery indicator showed that almost the entire contents of the battery had been consumed. On the arrival of the carriage at the electric light station in Thompsonville it was noted that the carriage was rapidly slowing down, although it was very plain that the batteries were still "willing." This characteristic of the electric storage battery to respond even to the most abusive loads is one of its most useful peculiarities, which, when understood, gives it a warm place in the heart of the motor carriage driver, and insures the electric carriage a permanent place in those fields where its limited radius of action is of small importance. Not until the last bit of current has been removed will it yield, and even then, after a short rest, it makes an effort to do one's bidding. A good storage battery is like a good dog.

The batteries were completely filled at Thompsonville. The return trip over the road to Windsor Locks was a very rapid and most enjoyable one, and owing to the daylight and the publicity of the occasion, considerable excitement was caused along the road. Although carriages equipped with other kinds of power have passed along this road in the past, the fact that this was the first "motor voiture de luxe" prevented any diminution in the interest shown. Windsor Locks was passed at a good twelve-mile gait and Windsor reached without a stop from the time we left the electric light station at Thompsonville. The distance between the two places is between twelve and fourteen miles and the time occupied in making it was one hour and five minutes.

A short stop was made at the Eddy Electric Company, through the courtesy of whom we were able to carry out our intention to ascertain officially the availability of current on subsequent trips through Windsor and to make a specimen charge, after which the return trip was resumed. The works of the Eddy company are eight miles from the place where the carriage is kept at Hartford, and the time occupied in making the run was forty minutes. The arrival home completed what is probably the first country trip of any electric carriage, the use of which, it is now apparent, is in some localities in fields beyond those to which its essential peculiarities ordinarily confine it. The makers of the Columbia carriages issue with their vehicles an interesting little pamphlet giving such information as is necessary to extend this field to the utmost, including a list of the principal charging stations in some of the Middle and Eastern States.

It was found on the trip that the cost of electric current at the different electric light stations was such as to make the cost of running between $1\frac{1}{2}$ and 2 cents per mile. In the smaller country stations the charges are high, but in the large cities the charges are such as to make the cost of running comparable with those of gasoline carriages. Six cents per kilowatt hour is the average price charged at large stations, resulting in a cost per mile of $1\frac{1}{4}$ cents.

To ascertain the ability to make an extended tour in the Eastern States, an examination into the location of the different electric light stations was made by the writer. The results of this investigation indicated that, starting from, for instance, Hartford, current could be obtained at intervals which would enable an electric carriage to easily run to Boston. Current is obtainable at Thompsonville, Conn.; Springfield, Mass., which is twenty-nine miles from Hartford; Palmer, which is sixteen miles from Springfield; Warren, which is eleven miles from Palmer; South Spencer, which is eleven miles from Warren; Worcester, which is seventeen miles from South Spencer; Westboro, which is thirteen miles from Worcester; South Framingham, which is ten miles from Westboro; Wellesley, which is seven miles from South Framingham; Newton, which is eight miles from Wellesley; and Boston, which is seven miles from Newton. Of course, there would be no need of stopping at all these stations, as the batteries in the Columbia carriage are good for twenty-five miles on ordinary country roads.

In the first part of the eastward trip from Springfield the roads are very hilly and sandy, and it is probable that the mileage of the batteries here would not be greater than twenty; but, even so, it is seen that electric light facilities are ample.

Going westward from Hartford, it was found that electric light stations where current is available are located at New Britain, ten miles from Hartford; Meriden, ten miles from New Britain; New Haven, nineteen miles from Meriden, but between which there are large mills using electric lights and willing to sell it to carriage users; Naugatuck, which is thirteen miles from New Haven; Bridgeport, which is five miles from Naugatuck; South Norwalk, which is fourteen miles from Bridgeport; Stamford, which is eight miles from South Norwalk; Port Chester which is eight miles from Stamford; Mamaroneck, which is five miles from Port Chester; Mount Vernon, which is seven miles from Mamaroneck; and Forty-second Street, New York City, which is fourteen miles from Mount Vernon. In New York current is available in almost any locality, even at many private residences.

In running out of New York it is found that the electric light stations up the Hudson River toward Albany are at near enough intervals to make touring also possible, and the same is the case between New York and Philadelphia. In the vicinity of Philadelphia the facilities are not quite so good in all directions, although the most enjoyable trips are in the direction in which electric current is available.

The only disadvantage that can be connected with the charging of storage batteries is the time required. In recharging mechanical carriages it is, of course, merely necessary to obtain the fuel. In the case of an electric carriage, however, a certain amount of time is necessary. In no case, however, unless the batteries are completely discharged or empty, is it necessary to take more than one and one-half hours. In many instances in the experience of the writer, the current consumed in a run of twenty miles has been returned in one and one-half hours.

Of course, at the present time the best recharging facilities exist in the Eastern States. It is probable, however, that even in the Middle-Western States the distances between stations where current can be purchased is so small that touring is possible whenever the condition of the roads would permit.

In this connection, and in conclusion, it may be interesting to state the number of towns and cities in the different Eastern and Middle States that have regularly equipped electric light stations. The following is a list:

Maine	30	New Hampshire	35
Vermont	23	Massachusetts	99
Rhode Island	12	Connecticut	34
New York	183	New Jersey	61
Pennsylvania	190	Delaware	5
Maryland	21	District of Columbia	2
Virginia	37	West Virginia	21
Ohio	138	Michigan	117
Indiana	96	Illinois	197
Kentucky	37	Iowa	106

* By Hiram Percy Maxim, in the Horseless Age.

A report of the United States Geological Survey states that coal getting machines are now being used to a greater or lesser extent in fifteen of the States. In 1896 the coal mined in these States by machinery amounted to 12,358,522 tons, or 13 per cent. of the aggregate output of those States for the year. The use of machines is likely to increase where they can be adopted with advantage.

BEESWAX ASSAY.

WAX analysis is not difficult, though unfortunately somewhat tedious, since no single test is available by which you are able to say that it is pure beeswax.

Beeswax is an important pharmaceutical substance, and also is extensively used in the arts.

Beeswax has, like that closely allied class of substances, the fixed oils, been the successful subject of the adulterator. Formerly it was largely adulterated with simple substances, such as flour, earthy matter, ferric oxide, etc. These still can often be found in wax, but are due as a rule to imperfect collection, and not as adulterations and makeweights. For the purpose of adulterating wax these obviously apparent admixtures have been supplanted to a large extent by use of other waxes so closely allied to the true beeswax that it now requires a careful and accurate analysis to detect them, identification often being impossible.

The Melting Point.—Different methods for the determination of this most important factor have from time to time been described, often one only being a modification of another.

The pharmacopœial method is naturally one which comes before us most prominently; the details given in the B. P. are familiar to all, and therefore need no explanation. The B. P., however, does not describe it quite accurately enough, for no mention is made of the fact that the melting point should not be determined until some hours have elapsed after the wax has been drawn into the capillary tube. This is a most important detail, for recently melted wax will remelt at a much lower temperature, and consequently you will obtain a lower result than is really the case.

The best way to determine this point by the capillary tube process is to work upon the lines indicated by the Hungarian Society of Analysts. They direct that the wax should be drawn up into a long capillary glass tube; seal the lower end, and attach it to the bulb of the thermometer in the usual way, so that the column of wax corresponds to the bulb of mercury. After twenty-four hours, place the thermometer into a glass test tube filled with glycerin and heat very gradually.

By observing details like these in such a test, the results are sure to be more reliable and comparable.

Pohl's process is a simple one, and yields very concordant results. The bulb of the thermometer is dipped into melted wax, so as to obtain a film of wax, then the instrument is fixed in a long clear glass test tube. After allowing the wax to become properly "set," which generally requires at least six hours, heat gradually by holding the tube containing the thermometer over a thick iron plate heated in the usual manner. The moment the wax forms a drop on the end of the bulb of the thermometer, note the temperature, which is the melting point.

Redwood proposes a modification of this method. Instead of placing the wax on the thermometer he lets melted wax (a small quantity) fall upon some mercury contained in a dish to which is attached a thermometer. Apply heat gradually, and the moment the wax disperses as a film observe the temperature, which is the melting point.

Specific Gravity.—For the determination of this essential point there are many various processes employed, but the majority of them depend on the use of special apparatus, generally of a most costly description, so there is no need to refer to them. On the other hand, there are several useful and accurate methods which can be employed without the expense of such appliances.

Hager's Process.—The essential feature of this method is to find the specific gravity of the liquid in which the wax will remain suspended in equilibrium.

The method of working this process is a simple one. Melt the wax gently and allow it to fall from a moderate height into some alcohol, 70 per cent. With practice a large number of beads of wax are formed.

These, after allowing time for contraction to occur, are placed in some previously diluted alcohol. To this either a stronger or weaker alcohol is added, until the beads are suspended in equilibrium at 15·5° C.

It is essential that the beads should be fully contracted, for from Dieterich's experiments it is shown that a very considerable error may arise by using the wax too soon after it has melted.

In consequence of this possible error, Chattaway and Allen prefer to cut the wax into small cubes and brush them over with a wet brush before immersion, to prevent the adhesion of air bubbles.

The specific gravity of the wax is therefore the specific gravity of this liquid, which can be determined in the usual manner.

According to Proctor, 100 grains of wax, with a five grain weight stuck in it, should sink in water, but should float with a three grain weight.

Solubility.—The solubility of a wax should also be taken into consideration. It is soluble in ether at 22° C. Insoluble in cold but completely soluble in boiling alcohol. Chloroform dissolves out about 25 per cent. in the cold, but completely dissolves it when hot.

CHEMICAL TESTS.

Determination of the Free Acids.—Beeswax contains cerotic acid, which is soluble in boiling alcohol, and is capable of being neutralized by an alkali. Advantage of this fact is taken by analysts in determining the purity of wax, since about 12 to 16 per cent. of cerotic acid is invariably present. If the wax were always pure, it would be a simple matter to calculate the amount of this acid, but as it is so frequently adulterated with other substances containing a free acid, the result of this test is generally referred to as the number of milligrammes of KOH necessary to neutralize the free acids in one gramme of wax. This is called "the free acid value."

Saponification Value (Koettstorfer's Number).—The second of the great chemical tests for wax is the saponification value, which is the measure of the amount of alkali — KOH — required to completely saponify the whole of the wax. In the previous case only the acid soluble in hot alcohol was estimated, but in this case the insoluble portion—myricin—is also estimated. The ester myricin or myricin palmitate is not saponified by an aqueous solution of potash, the reaction only occurring in alcoholic solution.

The ester value indicates the number of milligrammes of $\frac{\text{KOH}}{N}$ required to saponify the neutral esters in one gramme of wax. In obtaining the acid value that portion of wax soluble in hot alcohol was estimated—cerotic acid. In obtaining the saponification value the insoluble as well as the soluble bodies were conjointly estimated—cerotic acid and myricin—provided, that is, the wax was pure.

It is evident, therefore, that the ester value is the difference between the acid value and the saponification value, or, in other words, the saponification value is the sum of the acid and ester values.

In practice the easiest way to obtain these figures is to first ascertain the acid value, and then add the alcoholic alkali and proceed as described under saponification value. Then the amount of alcoholic KOH used corresponds to the ester value, and the total alkali, both aqueous and alcoholic, is necessarily the saponification value.

IODINE AND BROMINE NUMBERS.

Whether pure beeswax does absorb any appreciable quantity of the halogen is a somewhat doubtful point. Most of the great workers on this subject do not refer to this test, while a few give a very low and variable figure, that may, I think, be disregarded. These tests are most valuable when regarded from a negative standpoint. Pure beeswax, we may take for granted, absorbs little iodine and bromine, while, on the other hand, several of its most frequent adulterants do absorb a large amount, more especially carnauba wax and tallow.

Resin is frequently referred to by the authorities on this subject as a favorite adulterant, but as far as my experience teaches me, it is not generally used at the present time, except in prepared waxes for technical purposes.

Like stearic acid, it is apt to alter the specific gravity, making it considerably higher. Resin specific gravity = 1·045, 1·108, Lewkowitsch. It also gives a higher acid value unless compensated. If suspected it can be isolated conveniently by boiling the wax in 50 per cent. alcohol; filtering when cold, and evaporating the filtrate to dryness, and weighing the product. By using weak alcohol, stearic acid is not extracted.

It is obvious, therefore, that, though these processes are of great utility in analyzing beeswax, the results are not altogether conclusive. Every sample should be boiled with alcohol; when cold, filtered and an equal volume of water added to one part and an equal volume of solution of chloride of calcium to another. In each case the solution should remain bright and clear, precipitates indicating the presence of Japan wax, resin, tallow, etc.

In addition to these two tests, the wax of doubtful character should be submitted to the halogen test; absorption of either iodine or bromine at once points to the presence of a foreign body, most probably carnauba wax, tallow, or resin.—Read at meeting of Chemists' Assistants' Association.

INTERNATIONAL METEOROLOGICAL CONFERENCES.*

By ROBERT H. SCOTT, M.A., F.R.S., Secretary to the International Meteorological Committee.

THERE is no science so dependent on international concord for its successful prosecution as meteorology; and, consequently, for nearly half a century past such meetings as that which has recently taken place in Paris have from time to time been held.

The first and most famous of these assemblies had reference exclusively to maritime meteorology. It was held in 1853, in Brussels, mainly at the instigation of the late Commander M. F. Maury. Out of that congress grew a system of meteorological observations at sea, to be carried out in a uniform manner by all the nations represented at the congress. The form in which the observations were to be recorded is known as the "Brussels Abstract Log."

Looking back, in 1896, to the ideas of 1853, and to the fulfillment which has been made good in the space of forty-three years, the first matter calling for notice is that the United States, which took the initiative in convening the first congress, have completely given up their co-operation in the work of recent years, and are devoting themselves entirely to the preparation and issue of pilot charts.

Only three nations have continued to work up, with more or less fidelity, to the standard sketched out at Brussels—Holland, Germany and this country; each of which has produced contributions, of more or less extent and value, to our knowledge of the meteorology of the ocean.

Our own meteorological department of the Board of Trade, under Admiral Fitz-Roy, took its rise out of the Brussels congress. It was founded in 1854. In a letter from the president and council of the Royal Society, dated February 22, 1855, which has repeatedly been reprinted, we find that it was then contemplated that the meteorology of the entire ocean might be ascertained with a considerable approach to accuracy, by the organization then called into being. The impossibility of carrying out these wishes was not then fully realized.

After the Brussels meeting, matters, as regards international meteorology, slept for nineteen years. In 1872 an invitation to a free unofficial meeting at Leipzig was issued by three eminent meteorologists—Dr. Carl Bruhns, Observatory, Leipzig; Dr. Carl Jelinek, Meteorological Institute, Vienna; and Dr. Henry Wild, director of the Central Physical Observatory, St. Petersburg.

This conference was attended by fifty-two persons, representing most of the states of Europe, and inter alia it passed a resolution recommending the establishment of special offices for maritime meteorology in all countries where the requirements of navigation called for such a measure.

Out of the conference of Leipzig, the congress of Vienna, 1873, arose. This was summoned through diplomatic channels. There were thirty-two delegates present. As regards maritime meteorology it simply confirmed the resolutions of Leipzig, and further recommended the convening of a conference in London, for the discussion of the subject of maritime meteorology. This conference was held from August 31 to September 2, 1874, and was attended by twenty-four persons. Its deliberations were mainly directed to the discussion of the Brussels Abstract Log, and of the methods for reduction and publication of the observations.

Four years elapsed, and in 1878 a report on maritime meteorology* was drawn up for presentation to the projected meteorological congress at Rome. This report was published by the meteorological council, and it contains, in the several answers to a circular of questions issued in 1877, a very complete résumé of the arrangements for the prosecution of ocean meteorology in the various countries of Europe and in the United States. The replies from Commodore Wyman, Hydrographer to the United States, from Capt. Eaups, representing the Ministère de la Marine, Paris, and from Sir F. J. Evans, K.C.B., Hydrographer to the Admiralty, were particularly detailed and instructive.

The congress of Rome, 1879, was fully official, like that of Vienna, six years previously. It was attended by forty persons. Its action, as regards maritime meteorology, consisted in expressing its satisfaction with the mutual understanding which had been the outcome of the London meeting, and its opinion that perfect liberty should be left to the nations interested in making mutual arrangements for the prosecution of their work.

Since 1879, no congress has been held. The absurdity of summoning duly accredited representatives of governments, who were charged to announce to their colleagues that the authorities at home refused to be bound by congress resolutions, was apparent. The subsequent meetings of Munich, 1891, and of Paris, 1896, have not been official—in other words, they have not been brought together through diplomatic channels, but have been collected by circulars addressed to the heads of the meteorological services in the different countries.

At Munich, in 1891, the only mention of maritime meteorology was a request that methods of discussion and of publication of results should be uniform all over the world. Compliance with this demand was recognized as impossible, owing to the admitted inequality of distribution of material in the different oceans.

We now come to the conference of Paris in September last. At this no person, except Lieut. Kosslitz, from Pola, represented an exclusively marine establishment. Mr. James Page came from the Hydrographic Office, Washington, but only in a private capacity, not as representing his office. The questions which had direct reference to the sea, and which were brought up for discussion at the meetings, were few in number.

The first was a proposal from Dr. Paul Schreiber, the director of the meteorological service of Saxony, for the development and multiplication of observations of sea surface temperature over the North Atlantic. Dr. Schreiber gave no suggestions as to carrying out his proposal, and so the conference contented itself with recognizing the desirability of its realization.

Dr. Biese, of Helsingfors, head of the meteorological service of Finland, requested the conference to pass a resolution supporting his efforts to create a department for hydrography and maritime meteorology in Finland. The conference decided that in the case of Dr. Biese's request, and other similar proposals, inasmuch as the meeting had no official status, it was not in its province to pass any resolution which might in any way suggest a course of action to any government. It therefore placed on record its sense of the importance of the objects which Dr. Biese and others sought to attain.

More than one gentleman sent requests to the conference to institute investigations into the origin and phenomena of cyclones, but it was fairly remarked that it would not be an easy task to moor a cyclone to one spot, so as to allow of time for instituting observations all round its center!

Dr. Paulsen, chief of the Danish meteorological service, produced a series of very interesting charts, showing the monthly distribution of floe ice in the North Atlantic. The information from Greenland and Iceland is collected from Danish vessels making passages to those colonies; for the sea northward toward Spitzbergen it is furnished by Norwegian whalers. Dr. Paulsen requested any gentlemen who had access to observations from the North Atlantic, north of the sixtieth parallel, to send these data to Copenhagen for the completion of his charts.

Mr. C. L. Wragge, of Brisbane, head of the meteorological service of Queensland, brought forward various propositions relative to the importance of securing observations from high southern latitudes. The desirability of procuring such information was recognized as incontestable, but no opinion was expressed as to its practicability.

Dr. Snellen, director of the Meteorological Institute of the Netherlands, proposed a resolution of a very general character, which was adopted by the conference, to the effect that it was desirable that a special conference be called together to discuss the subject of maritime meteorology. No definite programme of subjects for discussion at this conference, if it ever comes to pass, has yet been put forward.

In this connection we must notice a paper which was prepared for submission to the Paris conference by Dr. G. Neumayer, the Director of the Deutsche Seewarte in Hamburg. Dr. Neumayer is well entitled to speak with authority on the subject; for more than forty years ago he was working, at the Flagstaff Observatory, Melbourne, on the meteorology especially of the Southern Indian Ocean, on the track of the Australian trade. In the paper now under consideration he gives a masterly summary of the condition of the science at present all over the civilized world, and expresses his hopes that uniformity of methods, etc., may be introduced, but without making any practical suggestions as to how the object can be attained. The great point which Dr. Neumayer urges is the necessity for a more or less free interchange of material between the different offices.

The difficulty in carrying this out lies in the expense involved in such a communication of information. It is universally admitted that the original logs cannot be handed about from office to office. Copies must be made, and the cost of copying soon grows to be over-

* Nautical Magazine.

whelming, for observations are required by tens and even hundreds of thousands.

The great difficulty of carrying out the idea conveyed in the letter from the Royal Society, already mentioned—that of publishing data for the entire sea surface—is at once evident when we consider that, in order to get observations, we must have ships, and ships will only be found along trade routes.

In the higher latitudes of both hemispheres the area from which materials are obtainable is strictly limited by the boundaries of ice prevalence.

In the South Atlantic Ocean observations are excessively rare from any parts except the belts marked by the tracks, outward and homeward, to and from the capes. In the Indian Ocean it is all but impossible to find observations for the vast region lying off the northwest coast of Australia.

As for the Pacific Ocean, no single part of it is covered with observations at all so thickly as even the less frequented parts of the other oceans.

We see, therefore, how much requires to be done before the meteorology of the sea can be held to have been thoroughly investigated.

As regards the proposal for a new conference, neither Dr. Neumayer nor Dr. Snellen has put forward a distinct programme, and without such a series of questions it is not easy to see how an invitation to a meeting has much chance of a favorable reception.

As regards the desirable uniformity of methods, the suggestions for work differ very widely. A few years ago an eminent Russian officer, Rear Admiral Makaroff, published the results of his observations in his ship, the Vitiaz, in the Pacific Ocean. In that volume he suggested far minuter work than has ever been attempted elsewhere. He asks that the actual day of the month on which an observation is taken should be stated, so as to show how the figures are affected by the season of the year!

In direct contrast to such nicety is the work turned out by the Hydrographic Office, Washington. This consists of pilot charts for each month, which fall out of date in a few weeks, and which Dr. Neumayer fairly describes as being ephemeral in character.

In conclusion, we regret that we are not able to say more than that the action of the Paris conference, as regards maritime meteorology, consisted in the registration of a certain number of good resolutions, without making any practical suggestions as to the methods for carrying them out.

THE CANOES OF THE MENOMINI INDIANS.

In the first part of the Fourteenth Annual Report of the Bureau of Ethnology to the Secretary of the Smithsonian Institution, 1892-1893, there is a very interesting and important monograph entitled "The Menomini Indians," by Walter James Hoffman, M.D. By the courtesy of the director of the Bureau of Ethnology we are enabled to present an engraving showing the setting up of a bark canoe, and our text is extracted from Dr. Hoffman's monograph.

The attention of some Menomini shamans who visited Washington was attracted by the work of the Bureau of Ethnology, and after protracted conferences the proposition was made by the chief, Niopet, that a visit to their reservation at Keshena, Wis., be made; that, after proper instruction by some shamans to be appointed, and due initiation into their society termed the Mitä´wit, their version of the traditions and dramatized forms of initiation should be studied, so that it could be preserved for the information of future generations of the Menomini. The first visit was made to Keshena in 1890, followed by four subsequent visits to attend to the necessary instructions and ceremonials of the society. It was during these visits that other new and interesting facts were obtained—material relating to their mythology, social organization and government customs, industries and linguistic germane to the subject in general. Space forbids even an outline of the interesting facts which are recorded in Dr. Hoffman's monograph.

The fabrication of Indian canoes is very interesting. The Menomini have almost entirely discontinued the making of the simple dugout and the birch bark canoe, and even among the old men but few are now recognized as having in their day been experts in this industrial art. The simpler form of boat was the dugout made of a single trunk, preferably that of a butternut

SIGNORA ZEFTHE AHAIRA.

tree. The wood is much heavier than most others available, but the Indians believe it resists better than any other variety the effects of long contact with water, as well as the erosion to which the bottom is subjected by frequent rowing in shallow streams in beds of gravel or bowlders.

The birch bark canoe is by far the most graceful piece of mechanism produced by the Menomini. The general form of the canoe differs to some extent among the various northern tribes. The type of canoe made by the Menomini resembles that of the Ojibwa, of Wisconsin, who are their nearest northern neighbors and with whom they have for many years maintained friendly relations, and to some extent intermarried. For their manufacture large birch trees that appear to furnish the best bark are selected and the pieces are cut as large as possible. These sections are sewed together with threads made of the long, thin roots of a species of spruce, a material durable and well adapted to a constant wetting.

The framework of the bark canoe is made of white cedar, which is durable, light and elastic. The ribs are thinned with a drawing knife, and when the required number have been made they are curved according to the parts of the canoe which they are intended to brace—the middle, of course, being much more distended laterally, while the ends gradually narrow to a point.

The tops of the ribs are held in place by being tied to a cross piece, the ribs and cross piece thus resembling a bow and its string. Then the entire series of ribs is fastened by tying to the longitudinal strips, corresponding to the gunwale, thus setting up the skeleton, as it were. These strips also are cut to the required thickness by means of a draw knife.

When the framework has reached this stage the bark, which in the meantime has been stitched together, is laid on the ground, the framework placed upon it, and then the bark is turned up over the sides; short posts are driven into the ground, all around the canoe, to hold the outside strips, to reinforce the edge or gunwale, and to prevent the breaking of the bark at the end. The appearance of the work at this stage is shown in our engraving. All the necessary stitching is then done to hold the tightly secured bark in place. The bow and the stern are still sufficiently unlike for the Indian to note which is the bow, for that end of the canoe, as in the dugout, is usually a little broader across the shoulders. The bottom of the canoe is lined with thin slats or shingles to protect the delicate bark from being broken. The seams, small punctures and knot holes are then sealed with pine resin.

Although the women have many duties to perform in connection with the building of a canoe—such as cord spinning, the stitching together of the pieces of bark and the final lashing of the long pieces forming the gunwale—the men usually do all the paddling when the canoes are in use.

The paddle is made of cedar or some other light wood. It measures about four feet in length, of which nearly one-half is devoted to the blade, which varies from four to six inches in width. Generally the top of the handle has two projecting pieces resembling a letter T, giving the oarsman an easy and effective means of holding and using the paddle. When not in use, the canoe is always pulled ashore and turned over, in order to allow the bottom to dry.

MENOMINI INDIANS SETTING UP A BARK CANOE.

SIGNORA ZEFTHE AHAIRA.

On October 18, Prof. Dr. Haberda, the Instructor of Medical Jurisprudence at the Vienna University, brought into his clinic one who appeared to be a small man with a heavy beard and mustache, and the students were greatly surprised to learn that this person was really a woman, although her strongly marked countenance, with its beard, her manner and bearing, and even her voice, were most masculine. Signora Zefthe Ahaira is thirty-three years old and was born in Tunis of Italian parents. She is the sixth in a family of fifteen children and the only one that developed any abnormality. She did not remain long in the convent in which she was to have been educated. At the age of fifteen she married and gave birth to a normal child, which, however, did not live long. As she and her husband were not happy together, they were soon divorced. Before her marriage, and while she lived with her husband, she kept her beard shaved, so that her appearance would not attract attention; but as the constant shaving became burdensome, she decided to let it grow and to adopt men's clothing, which she has worn uninterruptedly for a number of years, with the permission of the Italian authorities. She has conducted herself so like a man that no one suspected her of belonging to the "weaker sex," the impression thus conveyed being intensified by the manly tones of her voice. Prof. Haberda considers her a remarkable specimen of hermaphroditic formation. She is going to make a tour of Europe and America to give specialists a chance to study her.—Illustrirte Zeitung.

Cement pipes are made cheaply by an ingenious process devised by a French inventor. A trench is dug and the bottom filled with cement mortar. On this is placed a rubber tube covered with canvas and inflated; the trench is then filled up with cement. As soon as this is set the air is let out of the rubber tube, which is then removed and used again in another section. By this method six-inch pipes have been made at a cost of twenty-two cents a yard.

ACANTHOPANAX SESSILIFLORUM.*

ALTHOUGH, as the references show, this cannot be considered a new plant even in gardens, yet it is comparatively little known. We met with it in fruit lately in the nursery of M. Lemoine, at Nancy, and with the predatory instinct of the botanist, secured a specimen for the benefit of the readers of this journal. It is a handsome shrub, presumably perfectly hardy, with long stalked, palmately three-lobed leaves, the lobes leathery, dark green, broadly lanceolate, and tapering at each end, finely serrate at the margins. The flowers, which we did not see, are in globose heads, and are succeeded by black berries, each the size of a small pea, and reminding one of privet berries, or still more of ivy berries. The shrub is a native of the Amoor region, of the coast of Manchuria, and of North China. —The Gardeners' Chronicle.

A NATURALIST'S SOJOURN IN THE CRATER OF MAUNA LOA.

WHEN, at noon on August 8, I stood alone at the edge of the crater of Mokuaweoweo, my feelings were of a somewhat mixed character, says Dr. H. B. Guppy, of Hawaii, in the Pacific Commercial Advertiser. I had just said good-by to Mr. John Gaspar, who had brought me up, and before me lay a period of solitude of three weeks or more. From a previous ascent made on April 1, I gathered that it would be very cold, but beyond this I knew nothing of the climatic conditions to which I would be exposed. However, I set to work at once to arrange the interior of my tent, got out my meteorological instruments and planned my examination of the crater.

Before many days had passed it became apparent that the conditions of my existence were not unlike some of those to be found in the moon. In the complete sterility of the surface, in the very existence of the grim old crater, at the edge of which I had pitched my tent, in the rarefaction of the atmosphere, in the intense dryness of the air, as indicated by observations on the relative humidity; in the prevailing cloudless sky by day and in the clear starlit calm and dewless nights; in the severe cold at night and in the scorching of the sun in the day, there were produced many of the conditions we would look for in that planet. Then, again, the air at first was highly electrified. My red blanket crackled under my hands at night and I could trace on its surface in phosphorescent lines with my fingernail the letter A as I lay completely enveloped in its folds. The detached wings of dead butterflies picked up from the ground adhered provokingly to my fingers, and I began to imagine myself an electric battery. The effects of these meteorological conditions soon showed themselves in the cessation of the action of the skin, in severe headaches and sore throat; in a tendency to palpitation and dyspnea, and in sleeplessness, general lassitude and loss of appetite, most of which symptoms I attributed to the great lack of moisture in the air. I began seriously to think that Mr. Gaspar would find a mummy on his return, when a short spell of damp weather intervened, and, most of the unpleasant symptoms having disappeared, I began to take more interest in my surroundings.

And soon I found that I had a regular visitor twice a day in the shadow of the long mountain. For about twenty minutes after sunrise and before sunset the shadow of the mountain was thrown back against the sky of the opposite horizon. It seemed as if some Titanic brush had been at work on the sky far away, and had worked in the profile of the mountain with a very uncanny blue. Most evenings I used to light my pipe and watch the arrival and disappearance of the old mountain's shade. The peak was the last to go, and that was the signal for my retiring for the night. I was in the habit of getting up three or four times in the night to make observations of the wind and weather. At 1 A. M. on August 9 there was a most beautiful lunar halo, displaying most of the rainbow hues, the purple inside and the orange outside being most conspicuous. This was repeated in a less marked degree in the following night, and after that the phenomenon disappeared.

During my sojourn on the mountain top there was very little rain, only about 30-100 of an inch. Most of the rain on the summit fell during the night of August 12-13, and in that night I had an uncomfortable time of it. The wind was very gusty and was apparently disposed to lift up my tent and carry it bodily into the crater. It was bitterly cold, and I lay down with my boots on, lit my pipe and prepared for the worst. The canvas was reeking with the wet, and every fresh gust of the biting norther seemed to promise to deprive me of my shelter. Nature, however, came to my aid.

After sunset it began to freeze hard, and before long the canvas of my tent was as stiff as a board and no longer swayed to and fro with each gust of wind. I then fell asleep for an hour or two, and woke up to find the wind blowing strong from the south. A rapid thaw had set in, and the canvas was again soaking with wet, the water running down on my stores. This was repeated during the night, and to vary the entertainment there were two earth tremors, lasting in each case a few seconds. My tent, however, held bravely on. Sleep came to me in the early morning, and when I woke the sun was high up and there was a genial warmth in the tent.

The cloud effects were often magnificent. The snow-white sea of cumuli that gathered in the forenoon round the mountain slopes usually concealed the Kohala Mountains, but as a rule failed to hide the summit of Hualalai, and probably the level of its upper limit is on the average between 6,000 and 7,000 feet. Except on the few occasions when there were rain clouds about, the summits of Haleakala and Mauna Kea were always visible. On the forms and movements of the clouds I made regular observations. Perhaps the most striking phenomenon was that of the evanescent cirrus. In one minute the observer may be gazing at a cloudless sky overhead. In the next there appears as if by magic a large white cloud, which, being at no great elevation, is carried rapidly across the zenith and dissolves away in the course of a few minutes. The history of one of these clouds may thus be traced. The spectator looking, we will say, to the east, sees only the clear blue of a cloudless sky. Then suddenly a tiny white speck appears and in a few minutes the speck becomes a conspicuous cloud. In less than half a minute it has attained considerable dimensions, and as it is borne rapidly westward it exhibits violent commotion in its interior, frequently changing its form and in a few minutes melting away altogether. Sometimes, when there were a number of these cirri visible, the heavens presented quite a bewildering spectacle in quick appearance and disappearance of the clouds and in their frequent change of form.

There was a continual struggle between the northerly and southerly winds on the summit, the vicinity of my tent in the middle of the west side of the crater being their frequent battle ground. At such times miniature whirlwinds carried up sand and paper into the air, and if the tent was open, its interior became filled with dust. On the north and east sides the wind was usually northeast and easterly. On the south side it was south and easterly, while on the west side north to northwest and southwest to south-southwest were the prevailing directions of the wind, but the wind was rarely strong at the camp. One morning I left my tent at 7 o'clock with a light southerly breeze blowing, but after proceeding about half a mile to the north I found myself facing a bitterly cold northeast gale, against which I could scarcely stand, so that my purpose of going around the crater had to be abandoned for that day. Returning to the tent, I met the northerly wind once more.

My descent into the crater was made on the northwest side. It was a tedious operation, and one had to tread warily on the loose bowlders, that are often inclined to roll down and crush the intruder on his way. As soon as I reached near the center of the great pit the clouds began to pour in on all sides over the lips of the crater. In a few minutes I was enveloped in a dense mist, and any further observation was rendered impracticable. During the prevailing dry, clear weather with a cloudless sky, "smoke" is only evident in two places in the crater, one near the center and the other in the southwest corner from the base of a yellowish cliff, where there are apparently extensive deposits of sulphur. When, however, the sky is clouded, and especially when the air is moist, white vapor may be seen arising from the greater part of the surface of the crater. The change is a little startling, the true explanation being that a large amount of the vapor evolved is only visible in cloudy, murky weather. It is, therefore, possible that the accounts of two observers may vary greatly as to the crater's condition, and yet no difference in the condition actually exist. This especially applies to the district on the south and southwest borders of the crater, stretching about a mile to the southward. In cloudy weather white vapor arises from many places in this area. Many of these cracks and fissures exhibit evidence of having originally given passage to vapors at a very high temperature. The red glaze that coats their sides could never have been produced by the comparatively cool vapors now discharged from them. I should judge that the subterranean heat is now more actively displayed in the district extending a mile to the south of the big crater than in the crater itself. A very large amount of vapor is discharged from the borders of a small crater lying near Pohaku Hanalei, and this is probably the smoke sometimes observed from the Kona coast. One may expect that the next eruption will occur on this, the south-southwest slope of the mountain.

Curiously enough, insects of various descriptions are common on the summit. One species of butterfly common at the coast is not at all infrequent. The butterflies were more often to be found dead than alive, and those flying about were in a half drowsy condition and easily caught. There were flies of different kinds, the house fly and the bluebottle fly proving a great nuisance in my tent. Besides these there were moths, bees, gnats and an occasional dead dragon fly, while bugs and other insects were collected as they fed upon the bodies of the dead butterflies. These insects were more common when the wind was southerly, and no doubt they had been brought up to this absolutely sterile region by the wind. Evidently most, if not all, of the butterflies and moths soon die and probably the other insects, too. The whole matter is, however, very suggestive and shows how readily insects, even the parasitical bug, may find their way into the upper air currents.

During the last few days of my stay on the summit I found myself getting sensibly weaker, which I attributed partly to want of sleep and partly to lack of appetite. The kerosene had got mixed with the biscuit on the way up, and the sugar was in the same condition. Fancy also gave the same flavor to the bacon and rice, and I swallowed my food like so much sawdust. My face was like that of a coal heaver, washing being rather risky at that altitude. On the last day, however, I made myself a little respectable and awaited the arrival of the relieving party. When, therefore, on the evening of August 30 I heard the sound of voices, and the clatter of horses' feet outside the tent, I was not long in giving the party a welcome.

ACANTHOPANAX SESSILIFLORUM—BERRIES LUSTROUS BLACK.

A WORD TO MAIL SUBSCRIBERS.

AT the end of every year a great many subscriptions to the various SCIENTIFIC AMERICAN publications expire.

The bills for 1898 for the SCIENTIFIC AMERICAN, the SCIENTIFIC AMERICAN SUPPLEMENT, and the ARCHITECT'S AND BUILDER'S EDITION of the SCIENTIFIC AMERICAN are now being mailed to those whose subscriptions come to an end with the year. Responding promptly to the invitation to renew saves removing the name from our subscription books, and secures without interruption the reception of the paper by the subscriber.

PRICES.

The Scientific American (weekly), one year	$3.00
Supplement of the Scientific American (weekly), one year	5.00
Architect's and Builder's Edition of the Scientific American (monthly), one year	2.50
Export Edition of the Scientific American (monthly, in Spanish and English), one year	3.00

COMBINED RATES.

The Scientific American and Supplement	$7.00
The Scientific American and Architect's and Builder's Edition	5.00
The Scientific American, Scientific American Supplement, and Architect's and Builder's Edition	9.00

This includes postage, which we pay. Foreign subscribers not within the international postal arrangement should remit one dollar extra for postage. Remit by postal or express money order or check to order of Munn & Company, 361 Broadway, New York.

A NEW division in the middle ring of Saturn has been detected by Prof. Schaeberle. It is only partial, and is about the same width as Cassini's. Prof. Schaeberle thinks the division is not complete and that intervening matter reflects light so well that it is difficult to detect the division.

ON COMPUTING THE RADII OF AN ACHROMATIC OBJECTIVE.

By CHARLES L. WOODSIDE, Boston, Mass.

It is not the intention of the writer in this paper to discuss the comparative values and particular merits of the various forms of achromatic objectives, but to place before the reader a simple and effective means by which the radii of the four surfaces of such an objective may be easily and correctly obtained.

When, several years ago, the writer decided to grind an achromatic of five inches aperture, he found that the determination of the proper curves was no easy task, and although the lenses might have been ground on curves similar to some others, yet the element of uncertainty in the result was so great, owing largely to the fact that nothing was known of the refractive or dispersive powers of the glass which was intended to be used, that the writer decided to investigate the subject, first theoretically, then practically, in the hope of evolving some simple method of ascertaining the proper curves under such conditions; and, while no claim is made for originality of treatment, the writer hopes that the results of his experience may be worth recording for the benefit of those who are endeavoring to obtain objectives for themselves by their own handiwork.

The formula employed in computing the radii is practically that of Littrow, and an objective constructed according to this plan will have its crown lens double convex and its flint lens double concave generally, though sometimes concavo-convex. The first two surfaces, I and II, reckoning from the front of the objective, will always be of equal radii; III will be of nearly the same radius as II, and in certain cases the radii of I, II and III may be alike, while IIII will usually be of long radius, nearly flat.

In the making of an objective, if the indices of refraction and the ratio of the dispersions of the two pieces of glass are known, the four radii and resulting focal length may be computed with reasonable exactness before the work begins; but, if these quantities are not known, they must be assumed, and the resulting focal length will therefore be uncertain within small limits until the work has reached a certain stage of completion.

Presuming, then, that these quantities are known, we have:

μ = mean index of refraction } of the crown glass.
$D\mu$ = dispersion
μ' = mean index of refraction } of the flint glass.
$D\mu'$ = dispersion
λ = ratio of the dispersions.
δ = ratio of the dispersive powers (that is, the dispersions combined with the refractions) = ratio of the focal lengths of the lenses.
I = radius of the outer surface } of the crown lens.
II = radius of the contact surface
III = radius of the contact surface } of the flint lens.
IIII = radius of the outer surface
f_1 = focal length of the crown lens.
f_2 = focal length of the flint lens.
F = focal length of the objective.

Let us first compute λ, which we use as the argument of the "Table for Computing Radius III," thus:

$$\frac{D\mu}{D\mu'} = \lambda \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

and then compute δ, the ratio of the dispersive powers (and consequently the ratio of f_1 to f_2, inasmuch as the focal lengths of the lenses must be proportional to the dispersive powers), thus:

$$\lambda \div \frac{\mu - 1}{\mu' - 1} = \delta \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Having determined upon the focal length of the objective, we next compute f_1 thus:

$$F \times \frac{1 - \delta}{\delta} = f_1 \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

and f_2 thus:

$$f_1 \times \delta = f_2 \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

We now compute the radii of I and II thus:

$$f_2 \times 2 \times (\mu - 1) = I = II \ldots\ldots\ldots\ldots (5)$$

and then referring to the "Table for Computing Radius III" on next page, and using λ as the argument, we take out the quantities α, β and γ, and compute III thus:

$$f_2 \times \left[\alpha + \left(\beta \times (\mu - 1{\cdot}50)\right) + (\gamma \times (\mu' - 1{\cdot}60))\right] = III \ldots (6)$$

It only remains for us to compute IIII thus:

$$\frac{III \times \left(f_1 \times (\mu' - 1)\right)}{III - \left(f_1 \times (\mu' - 1)\right)} = IIII \ldots\ldots\ldots\ldots (7)$$

and we have the complete data for the construction of the objective.

Let us, for example, compute the radii of an objective of 60 in. focal length, using hard crown and dense flint glass, for which we find that:

μ = 1·52
μ' = 1·63
$D\mu$ = 0·014
$D\mu'$ = 0·028

$$\lambda = \frac{0{\cdot}014}{0{\cdot}028} = 0{\cdot}5 \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

$$\delta = 0{\cdot}5 \div \frac{0{\cdot}52}{0{\cdot}63} = 0{\cdot}60577 \ldots\ldots\ldots\ldots (2)$$

F = 60 in., and

$$f_1 = 60 \times \frac{1{\cdot} - 0{\cdot}60577}{0{\cdot}60577} = \frac{0{\cdot}39423}{0{\cdot}60577} = 39{\cdot}0474 \ldots\ldots (3)$$

$$f_2 = 39{\cdot}0474 \times 0{\cdot}60577 = 23{\cdot}6537 \ldots\ldots\ldots (4)$$

$$I \text{ (and II)} = 23{\cdot}6537 \times 2 \times 0{\cdot}52 = 24{\cdot}5998 \ldots\ldots\ldots (5)$$

From the Table, with $\lambda = 0{\cdot}5$ as the argument, we find that $\alpha = 1{\cdot}00273$, $\beta = 1{\cdot}331$ and $\gamma = 0{\cdot}623$; hence,

$$III = 1{\cdot}00273 + (1{\cdot}331 \times 0{\cdot}02 = 0{\cdot}02662) + (0{\cdot}623 \times 0{\cdot}03 = 0{\cdot}01869) = 1{\cdot}04804 \times 23{\cdot}6537 = 24{\cdot}7900 \ldots\ldots (6)$$

$$IIII = \frac{24{\cdot}79 \times (39{\cdot}0474 \times 0{\cdot}63)}{24{\cdot}79 - (39{\cdot}0474 \times 0{\cdot}63)} = \frac{609{\cdot}8305}{0{\cdot}1902} = 3206{\cdot}26 \ldots (7)$$

Therefore, we have—

I	24·60 in.
II	24·60 "
III	24·79 "
IIII	3206·26 "
F	60·00 "

It will at once be seen that the computation of the radii is extremely simple and direct, and requires no more knowledge of arithmetic than is commonly acquired in our public schools.

It has been stated above that in certain cases the radii of I, II and III may be made of equal length. The condition upon which this depends is that the computed radius of II (and I) must be slighter shorter than that of III. Such being the case, the radii of I and II may then be increased to equal that of III and the lenses separated a certain small distance exactly equal to the increase in focal length of the crown lens resulting from the increase in the radii of I and II. It may be remarked, however, that the distance by which the lenses are separated must not be large, and ought not in any case to exceed say one twenty-fifth of the focal length of the crown lens. It should also be noted that, although the actual focal length of the crown lens is increased, its equivalent or effective focal length remains unchanged, inasmuch as the separation reduces the power of the crown lens and thereby exactly compensates the increase of the focal length in its effect upon the chromatic and spherical aberrations; so that the value of f_1 becomes $f_1 - d$, and this expression is to be used in all cases where the lenses are separated, to represent the value of the focal length of the crown lens.

If an objective is to be constructed upon this plan, we compute the radii of the four surfaces in the usual way and then find the distance, d, by which the lenses are to be separated, thus:

$$I - \frac{II}{III} \times f_1 = d \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

and then simply make the radii of I and II of the same length as III.

If we take, for instance, the previous example, we find that the radii of I and II = 24·60, while that of III = 24·79. The radii of the crown being shorter than III, the condition of separation is fulfilled and we compute the distance between the lenses, thus:

$$I - \frac{24{\cdot}60}{24{\cdot}79} = 0{\cdot}00772 \times 23{\cdot}6537 = 0{\cdot}1826$$

The radii of the objective will then be—

I, II, III	24·79	inches.
IIII	3206·26	"
d	0·1826	"
F	60·00	"

By this method of treatment, we have an objective at once effective, extremely simple in form and comparatively easy to produce, inasmuch as it requires but two pairs of tools, an item of no small consequence to the amateur. It may be urged, upon theoretical grounds, that the separating of the lenses is not conducive to the very best results; and while this is undoubtedly true when the separation is quite considerable, yet if the limit already named is not exceeded, the practical advantages of the form very much more than compensate any theoretical objection. In this connection it may be stated that the Clarks have separated the lenses of all their later large productions, including the 36 in. Lick objective.

Let us presume now that the objective is to be made from two pieces of glass, of the refractive and dispersive powers of which we know nothing. It is evident, from what has already been said, that the quantities μ, μ', λ and δ must be known before the radii of the objective can be computed. We must, therefore, proceed in a manner practically the reverse of that already employed, and first form the glass into lenses from which we may deduce these quantities with great accuracy, by the aid of which we may then compute the radii of the four surfaces in the usual way and complete the objective.

In the absence of any definite knowledge of the constitution of the glass, we must assume μ and δ, and upon the correctness of these assumptions will the focal length depend to some extent.

Perhaps the best and clearest way of showing this method of procedure is by a practical example from my own experience, in the making of a 5 in. objective. The two pieces of glass for this objective were obtained at different times, and beyond the fact that they were made by Feil, nothing was known concerning their optical properties. The ratio of their dispersive powers, δ, was assumed to be 0·63, from which it was found by equation 3 that for an objective of 62½ in. focal length, f_1 should be 36·70 in.

$$62{\cdot}5 \times \frac{1{\cdot}00 - 0{\cdot}63}{0{\cdot}63} = 36{\cdot}70$$

and by equation 4 that f_2 should be 23·12.

$$36{\cdot}70 \times 0{\cdot}63 = 23{\cdot}12$$

Next, the index of refraction of the crown glass, μ, was assumed to be 1·51, and the radii, I and II, necessary to give the required focal length, f_1, were found by equation 5 to be 23·58 in.

$$23{\cdot}12 \times 2 \times 0{\cdot}51 = 23{\cdot}58.$$

As these computations were approximations only, the radii of I and II were made 23·50, and one pair of tools was prepared of that curvature. Work was then begun on the crown lens, and it was ground and polished complete, great care being exercised in keeping the surfaces as true as possible to the curve. The front surface of the flint lens, III, was then ground with the convex mate of the tool used in grinding the crown lens, and for the back surface, IIII, a tool was used of 270 in. radius (which had strayed into my possession at some previous time) and these surfaces were then polished. Had not this tool been at hand, it would have been necessary to grind IIII of the same radius as III; but, had this been done, then only a little more than one-half the diameter of the lens (say 3 in. of a 5 in.) would have been ground, as, otherwise, the lens would be made too thin at the center, because of the great curvature of the tool.

After the lenses were polished, the exact radius of curvature was obtained by the reflection of light from the surfaces of the flint lens. This was easily done by means of a tin screen, through which a large pinhole had been made, placed around a light, the rays of which, emerging from the pinhole, impinged upon the concave surface of the lens and were reflected back to an eyepiece placed near the pinhole. The best arrangement was to fix the screen and eyepiece about 4 in. apart, on a piece of board, which could then be placed upon a table and moved back and forth, farther from or near to the lens, as occasion required. It should be noted that the movement of the board should be as nearly as possible in the line of the optical axis of the lens, and that the pinhole and the thread of the eyepiece must be at equal distances from the lens at all times. The tin screen should entirely surround the lamp and be several inches taller than the lamp chimney; and the pinhole should be opposite the bright part of the lamp flame. A low power positive eyepiece should be used, with a fine silk thread placed exactly in its focus. The lens was now focused carefully until a good clear image of the pinhole was obtained, and the distance was then measured from the surface of the lens to the thread of the eyepiece (or the pinhole), which distance represented the actual radius of that surface of the lens.

The radius of III was found to be entirely correct, being 23·50 in.; but that of IIII was slightly longer than the radius of the tool and measured 278 in.

The radii of I and II cannot be obtained in this manner, but as I, II and III were all ground on the same pair of tools, it was safe to assume that all were of the same radius.

The glass had now been formed into lenses of known radii and from them was to be ascertained, by actual trial, their true focal lengths and their optical properties.

The crown lens was then mounted in a tube, and in front of the lens was placed a diaphragm which cut off all the rays of light except a ring or zone about one-quarter inch wide, midway between the center and edge of the lens. The eyepiece with the thread in its focus was used, and the whole carefully focused on a bright star. The focal length was then measured from the middle of the edge of the lens to the thread of the eyepiece, parallel to the optical axis of the lens, and the mean of several trials was 22·82 in. The quantities, I, II and f_1 now being known, μ was found by the following equation to be 1·51480.

$$1 + \frac{I \times II}{(I + II) \times f_1} = \mu \ldots\ldots\ldots\ldots\ldots\ldots (9)$$

$$1 + \frac{23{\cdot}5 \times 23{\cdot}5}{(23{\cdot}5 + 23{\cdot}5) \times 22{\cdot}82} = 1{\cdot}51480$$

The lenses were now mounted together, the surfaces, II and III, being in contact with each other. The focal length, F, of the combined lenses was then measured as before from the same points, and found to be 66·82 in. Then, by the following equation the focal length of the flint lens, f_2, was found to be 34·655 in., thus:

$$\frac{F \times f_1}{F - f_1} = f_2 \ldots\ldots\ldots\ldots\ldots\ldots (10)$$

$$\frac{66{\cdot}82 \times 22{\cdot}82}{66{\cdot}82 - 22{\cdot}82} = 34{\cdot}655$$

and by the following equation μ' was found to be 1·62526.

$$1 + \frac{III \times IIII}{(III + IIII) \times f_2} = \mu' \ldots\ldots\ldots\ldots (11)$$

$$1 + \frac{23{\cdot}5 \times 278{\cdot}}{(23{\cdot}5 + 278{\cdot}) \times 34{\cdot}655} = 1{\cdot}62526$$

The lenses were again mounted in the tube, without the diaphragm, and gradually separated until the color correction was the very best that could be obtained. Great care was exercised in this test, and several different objects were tried—the moon, Jupiter, Saturn, thermometer bulbs in sunshine, etc.—and the separation of the lenses was best effected by means of paper and cardboard rings placed between them. The distance between the lenses was then measured carefully, the mean of several trials being 0·719 in. This showed that the focal length of the crown lens was too long by just the amount of separation required—that is, if f_1 had been 22·101 in., the objective would then have been achromatic when the lenses were in contact. From these quantities, then, $f_1 - d$ and f_2, the ratio of the dispersive powers, δ, was found by the following equation to be 0·63774, thus:

$$\frac{f_1 - d}{f_2} = \delta \ldots\ldots\ldots\ldots\ldots\ldots (12)$$

$$\frac{22{\cdot}82 - 0{\cdot}719}{34{\cdot}655} = 0{\cdot}63774$$

But while, for the purpose of obtaining the ratio of the dispersive powers of the lenses, the focal length of the crown was considered as too long by 0·719 in., on the other hand, the focal length of the crown may be considered as correct and the focal length of the flint as too short by a proportionate amount; and this latter view is the one which will be adopted in the further consideration of the subject.

The reason for this will at once be plain; for while to shorten the focal length of the crown lens involves the regrinding and polishing of two surfaces, the lengthening of the flint lens involves one surface only, that of IIII. It will be evident, too, that the crown lens, being equiconvex, will always be correct in form, and with the lengthening of the flint focus by the increase

TABLE FOR FINDING RADIUS III.

EXPLANATION.—The table is computed for a refractive index of 1·50 for the crown glass and 1·60 for the flint glass.

λ represents the ratio of the dispersions of the two lenses.

α represents the radius of the third surface (III), the unit of measure being 1.

β represents the factor to be multiplied by the variation of the crown index from 1·50.

γ represents the factor to be multiplied by the variation of the flint index from 1·60.

α, β and γ are then to be added together and their sum multiplied by the focal length (f_1) of the crown lens; the result will be radius III.

of radius, IIII, will be correct in focal length also; and the proper separation of the lenses, while effecting the color correction, at the same time brings the surfaces, II and III, into their proper relation with each other to correct the spherical aberration.

The optical properties of lenses were now all known quantities, and it remained to compute the distance, d, by which the lenses were to be separated, the focal length of the flint lens in order that it may be proportional to the ratio of the dispersive powers, δ, and the radius of IIII to produce this focal length.

First, then by Eq. 1, λ was found to be 0·52517, thus:

$$0·63774 \times \frac{0·51480}{0·62526} = 0·52517$$

and with this as the argument the quantities α (1·00601) β (1·369) and γ (0·935) were taken from the table and the distance between the lenses, d, was found by the following equation to be 0·2696 in., thus:

$$f_1 - \frac{II}{[\alpha + (\beta \times \mu - 1·50) + (\gamma \times \mu' - 1·60)]} = d \quad \ldots (13)$$

thus:

$$22·82 - \frac{23·5}{1·00601 + 0·02083 + 0·01527} = 0·2696.$$

Then, by this equation, f_2 was found to be 35·3598 in., thus:

$$\frac{f_1 - d}{\delta} = f_2 \ldots\ldots\ldots\ldots \quad (14)$$

$$\frac{22·82 - 0·2696}{0·63774} = 35·3598$$

and by Eq. 7, IIII was found to be 373·52, thus:

$$\frac{23·5 \times 135·3598 \times 0·02520}{23·5 - 135·3598 \times 0·02520} = 373·52$$

while the focal length of the objective, F, was found to be 62·249, thus:

$$\frac{f_2 \times (f_1 - d)}{f_2 - (f_1 - d)} = F \ldots\ldots\ldots\ldots \quad (15)$$

$$\frac{35·3598 \times 22·5504}{35·3598 - 22·5504} = 62·249.$$

Therefore, we have:

I, II, III	23·50	in.
IIII.	373·52	"
f_1	22·82	"
f_2	35·3598	"
F	62·2490	"
d	0·2696	"

The back surface of the flint lens IIII was then reground and polished, figuring of any kind having been carefully avoided, the object being to keep the surfaces as nearly as possible to the computed curves; after which the objective was tested and proved even at this stage of completion to be very nearly correct. The objective was then finished by figuring where necessary, and has since proved to be most satisfactory in its performance.

METHODS OF DETERMINING THE ECONOMIC PRODUCTIVITY OF MUNICIPAL ENTERPRISES.*

THIS topic must be defined and limited before it can be profitably discussed. Obviously, it does not cover all municipal enterprises. No practical object would be gained by a discussion of the economic productivity of roads or parks or sewers or police. It is needless to justify what everyone accepts. On the other hand, there are classes of municipal enterprises the economic productivity of which is a matter of controversy. Means of transportation within the municipality or public docks may serve as examples. If a municipal enterprise aims primarily at rendering an economic service, it may fairly be tested by its economic productivity, but otherwise not. Certain municipal enterprises are merely or mainly devices for rendering economic services cheaply and well. Their efficiency must be determined by comparing them with other devices for rendering equivalent services. The latter may be divided into private enterprises regulated mainly by competition and private enterprises regulated both by competition and by governmental interference. This leads to a final limitation of the question, viz., the methods of comparing the economic productivity of municipal enterprises aiming at economic production with private enterprises rendering similar services and more or less subject to governmental control. It may be noticed in passing that the final decision upon the wisdom or folly of such municipal enterprises must be influenced by many considerations besides the economic productivity of the ventures. The general theory of our law and political science is adverse to a wide extension of the functions of municipalities in such directions. The not infrequent corruption and the more frequent incompetency of our city governments are practical arguments in favor of the same position. On the contrary, the high-handed procedure of many corporations holding public franchises, an argument entirely aside from the present phase of the subject, is yet of great, perhaps of decisive, weight in forming the final conclusion.

The economic productivity of municipal enterprises may be measured only by comparing their efficiency with that of similar private enterprises. But the two have diverse ends in view. The aim of a municipal enterprise is to satisfy the voters; the aim of a private plant is to earn money for the corporation. Hence they are not likely to render the same service, except occasionally and by accident. To be sure, one most important means of pleasing the voters is by convincing them that their money is being saved and their taxes reduced. But perhaps as many voters would be influenced by a policy of generous or lavish display as by a favorable balance sheet. So, too, a most important means of earning money for a corporation is by pleasing not necessarily all the voters, but the patrons and possible patrons.

The fact remains, however, that the primary object in the two cases is different and that we cannot compare the economies of the two systems until one or the other of these ends or some intermediate one is made our standard. Perhaps we may say that the primary end is to protect the capital invested, whether private or public, and, if it be private, to secure a reasonable return upon what has been necessarily and legitimately expended, and that the further end is to render a satisfactory service to the consumers, who may often be substantially the entire public. If this be admitted, it follows that the true end is not that of the ordinary corporation or of the ordinary municipal enterprise, and that the former is likely to neglect the interests of the consumers and the latter to risk the capital of the taxpayers. Furthermore, the consumers may be grouped into two classes, the municipality as a body and the private citizens as individuals, and the balance must be held between these two interests, which are often antagonistic. It is not, I believe, uncommon for a private corporation seeking a contract or franchise to offer unduly favorable terms to the municipality and recoup itself for losses thus incurred by unduly high prices to individual patrons. Municipal enterprises, on the contrary, are tempted to close contracts with private patrons at a losing figure and let the municipality as a whole make up the losses.

The arguments upon the profitableness of municipal ownership differ so widely in the various enterprises that a statistical examination must lose in thoroughness and range if it seeks to include several classes under a single investigation. From the point of view of method, therefore, it would seem better to make a separate statistical study for each industry affording the requisite information. For this purpose gas lighting has been chosen as the one upon which the greatest amount of trustworthy information is available. The facts regarding the gas companies of Massachusetts have been gathered now for ten years, and evidence of certain changes may be derived from a collation of the facts contained in the eleven annual reports of the board of gas and electric light commissioners of that State. I may briefly recapitulate the changes which by way of extended illustration have been shown to have occurred, and presumably to be still progressing in Massachusetts, and not improbably elsewhere under the system of private control subject to state supervision.

(1) The manufacture of coal gas increased five-sixths in nine years.

(2) The proportion of this gas unaccounted for, and so attributable to leakage, has fallen to about three-fifths of what it was eight years ago.

(3) The quality of the gas has improved, especially in the case of the larger companies.

(4) The number of high power gas lamps and of gas stoves has been rapidly increasing.

(5) Meanwhile the number of public gas lights has fallen about two-fifths.

(6) The price of gas has been falling, especially among the larger companies.

(7) The proportion of the cost of coal obtained from the sale of residuals has been rising.

Now the point upon which emphasis is to be laid is that the changes to which every sort of enterprise is subject, and of which the foregoing are illustrations, are of far greater importance in the determination of its real economic productivity than the condition of that business at any point of time. Assume for the moment that all these gas companies had been managed for the last decade as municipal enterprises, would the same changes have taken place? If not, would those that did occur have resulted in a greater or in a less economic productivity? Such questions, it appears to me, are speculative and will be answered by every one in accordance with preconceived ideas or theoretical arguments. I see no way in which to wring a conclusive answer to them from experience. Accordingly the answer which as a statistician rather than a theorist I am compelled to make to the question at issue is, in the first place, that until municipal enterprises have had a longer history, and the facts have been gathered and presented in a shape suitable for comparison, no method of determining their economic productivity will give convincing results, and that, secondly, when the facts are obtainable, the conclusions must be drawn from the changes which are fostered by the various systems, and that the conditions prevailing under any one at a particular time must be deemed of subsidiary importance.

* Prof. Walter F. Willcox, of Cornell University, in the American Journal of Sociology, Chicago, November. Condensed for Public Opinion.

A PROFITABLE SPECIALTY—THE MANUFACTURE AND SALE OF FURNITURE POLISH.

LEON L. WALTERS points out (American Druggist) the fact that there are many widely used preparations the manufacture of which comes directly within the province of the pharmacist, and which, if properly pursued, become sources of very considerable trade and profit, and which tend greatly to offset the loss of trade in toilet articles, stationery and the like resulting from the fierce, and in many instances unfair, competition of department and other stores.

Prominent among the means that are open to almost every druggist as a profitable addition to his business is the making and selling of

FURNITURE POLISHES AND CREAMS.

The amount of these preparations used annually is very considerable, and with a little effort there is no reason why the druggist should not be able to command at least a portion of this trade.

The polishes most generally sold vary widely in their composition and utility, and it is difficult to devise a formula for any one polish to give uniform satisfaction. Formulas are, therefore, given for a number of polishes and creams, any one of which produces a tolerably good article.

Perhaps the most widely known and generally used

of furniture polishes is the one commonly designated as

"CHEMICAL POLISH."

	Parts.
Linseed oil	40
Alcohol	4
Vinegar	16
Antimony chloride	2
Ammonium chloride	1
Spirits of camphor	1

Place the oil in a large bottle, and add successively the antimony chloride, the spirits of camphor, the vinegar and the alcohol, part by part, and with constant shaking; when thoroughly incorporated, add the sal ammoniac.

This, perhaps, as an "all round" polish gives better satisfaction than any other. The following simpler formula has, however, during a trial of some four years proved very satisfactory. It is sometimes sold as

ACME FURNITURE POLISH.

Boiled linseed oil	4 pints.
Alcohol	2 "
Turpentine	1½ "
Antimony terchloride solution	10 drachms.

Mix the linseed oil and the turpentine; dissolve the antimony terchloride in the alcohol and add to the oil and turpentine little by little, shaking after each addition.

As a fair sample of polishes containing acids, the following may be taken:

ACID POLISH.

Boiled linseed oil	4 ounces.
Alcohol	3 "
Hydrochloric acid	2 drachms.
Red sanders, q. s. to color.	

Mix the oil with the alcohol; then add the acid with constant shaking.

As a renovating polish, the above is widely used. It should be shaken up before being used.

Pastes and creams, on account of their cleanliness and ease of application, are coming to be quite generally used. The formula given below produces an article that will compare more than favorably with any now on the market:

FURNITURE CREAM.

White soap	2½ ounces.
Spirits turpentine	80 "
White wax	20 "
Water	110 "
Carbonate potash	1 "

Place the soap in a water bath with a portion of the water and melt by a gentle heat, adding the remaining water as fast as absorbed. Now add the wax and increase the heat until it melts. Reduce the heat and add the turpentine gradually, stirring until all is thoroughly incorporated.

This produces an elegant article, which sells rapidly and gives even satisfaction. It should be put up in one and a half and two ounce ointment jars properly labeled.

THE SELLING OF THEM.

Two fields are open for the sale of the above: First, at retail to local trade and, second, in quantities to furniture dealers. For local trade there are two seasons in which special effort should be made to push the sale of the above, namely, during spring and fall house cleanings. At these times the judicious use of window displays, combined with appropriate, neat and striking signs, will be of great service. But of all the means at hand for calling your customers' attention to the fact that you make such preparations, perhaps the most efficient consists in the printing of a brief little folder with reference to furniture polishes alone. Such a folder, of say four pages (two double pages), costs but comparatively little, and, if properly composed, the results fully merit the outlay. Make it brief and concise, stating clearly and succinctly the good points of your polish, directions for its use, with a little explanation as to just why the druggist, above all others, is best fitted to know what constitutes a good furniture polish, and why he is eminently qualified to make it. During the seasons mentioned an admirable plan for distributing the folders is to inclose one in each package as it is made up. When thus carried out this method, combined with a judicious personal recommendation to customers while in the store, will seldom fail of the desired end.

The supplying of dealers with polishes of various kinds opens up a new field to many druggists. Every furniture dealer uses yearly a considerable quantity of furniture polishes and creams, which, as a rule, he buys from his wholesale dealer in bulk. I know of one druggist who derived a considerable revenue from supplying polishes to the furniture trade of his town, and there is no reason why others should not be equally as successful. Make up a small quantity of each of the different polishes for which formulas are given and send a sample of each to the furniture dealers of your city, accompanied by a circular telling of the advantages to be derived from purchasing his polishes from you, with an offer of putting them up to suit his trade. Such a letter, if properly worded and accompanied by the samples mentioned, seldom fails of a favorable reply. The manufacture of the polish need not detract in the slightest degree from the usual business of the druggist. The preparations can be made at leisure, and, what is more, they serve as a vehicle for the employment of discarded alcohol, such as has been used in the cleaning of mortars and the like, and which otherwise is of little value.

The charges upon cotton in New Orleans for storage and compressing are the same as those governing the trade last year, says the Textile World. We select the following charges, as they will be of interest to some of our readers: Storage for first thirty days on compressed cotton, 15 cents; extra charge for every additional thirty days, or part thereof, 8 cents; compressing, per bale, 30 cents; compressing and drayage to and from press, per bale, 60 cents; turning over cotton for marking, per bale, 3 cents; extra bands, 5 cents each; sample bale covering, per bale, 2 cents; sewing up heads, per bale, 3 cents.

ELECTRIC LOCOMOTIVE FOR MINES.

THE uses of electricity in mining are being extended continuously, and for propelling cars in mines electric locomotives present great advantages. One of the first applications of electricity as a propelling power on a commercial scale was made in the mines of the Harz Mountains, in Germany, by the well known firm of Siemens & Halske.

Our cuts show the electric mining locomotive constructed by the Union Elektricitäts-Gesellschaft, of Berlin, Germany. The compact arrangement of parts enables these engines to pass through narrow places, and uniformity of the exterior dimensions is preserved for engines of various powers, so that a 4 horse power engine is exactly like a 26 horse power engine in outward appearance. The outer frame is so constructed that it will receive motors of various powers, so that the design of the frame and its size are the same for all engines. The wheels can be shifted on their axles so that the engine will operate on railways of any gage from 490 millimeters (1 foot 8 inches) up to 650 millimeters (2 feet 1⅝ inches). As the gage used in mining railways varies, the adjustability of the wheels is a very useful feature.

The locomotive consists of a cast iron frame reinforced by flanges and supported on the axles by coiled springs. The motors are carefully incased, and have on their casings rearward projections forming bearings for the wheel axles. The connection between the motor shafts and the wheel axles is made by incased gearing. The switch for controlling the speed, starting the engine and reversing the motors is located at the top, near the end of the engine, so as to be readily accessible and yet occupy little room. The connecting wires are inclosed in tubes screwed upon the frame and are thus protected against injury by moisture or from other causes.

In the center of the engine is the contact arm carrying the trolley. This arm can move up and down to a considerable extent, so as to readily follow the line of the overhead conductor. When the rails can be used to form the return circuit, one trolley arm is employed; in other cases the engine is provided with two trolley arms. Sand is used to increase the adhesion of the wheels to the rails if necessary. A powerful hand brake serves to stop the engine and train.

Our third cut shows a 12 horse power engine with wheels adjustable to a minimum gage of 490 millimeters (1 foot 6 inches). The other cuts represent a 100 horse power engine developing a pull of 2,500 kilogrammes (5,500 pounds) at a speed of 2.5 to 3 meters (8 feet to 9 feet 10 inches) per second. The engine weighs 18,000 kilogrammes (40,000 pounds), and is shown as running upon a railway of 700 millimeters (2 feet 11½ inches) gage. For the engravings we are indebted to Der Stein der Weisen.

ELECTRIC PUMPS FOR BOILERS.

A RECENT article in L'Electricien, says the Western Electrician, by M. P. Simon, discusses at considerable length the question of water feed for steam boilers, dividing the necessities of the case under three heads. These are:

First. The water should be both chemically and mechanically as pure as possible.

Second. It should be fed into the boiler at as high a temperature as possible, being heated by waste steam only.

Third.—The feeding apparatus should be simple, economical and little liable to derangement or accident.

The third factor in the case appears to be open to more thorough discussion than the two former. In considering methods there seem to be but two which have place in the discussion—injectors and pumps.

The injector is open to serious objections. Its first cost is high. It can only be used economically with cold water; the quantity of water it is capable of handling is nearly a quite a fixed amount. If the water is heated for the injector it is expensive because of the loss of steam used for this purpose. In addition to these objections, the injector sometimes gets out of order, and requires time, during which the boiler must be supplied by another means, to repair, as it is at best a rather delicate piece of apparatus, though not very complicated.

Pumps, on the contrary, are extremely varied, of all forms, sizes and action. They are readily changed to suit all circumstances. The rated output may be doubled or trebled with ease, they will handle hot as well as cold water without difficulty. The system is capable of the greatest flexibility with the least inconvenience.

Where these are actuated directly by a pumping engine there is more work done at times than is required and the overflow runs back into the tank, making a loss of that much power. This sometimes amounts to two or three times the power utilized.

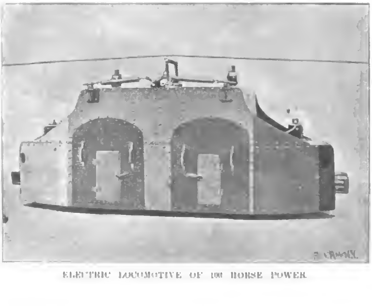
Putting these steam-driven pumps on a multiple system of boilers, where several are fed from one source, the complication of pipes, valves, etc., becomes burdensome and objectionable. When the pump is actuated by a driving belt, in case of constant demand and continuous supply, the same objections obtain. In general, an independent power supply is preferable, as indicated by the great number of donkey engines in use for such service.

But the engines consume an amount of power entirely disproportioned to the good achieved. This is not to be wondered at. As a rule, the smaller the machine, the less the efficiency. The author cites a pump which requires 400 kilogrammes of steam to produce one horse power of work.

There is an electrical method of disposing of the question. A motor, shunt wound, having a field rheostat, can be run at varying speeds and regulated with great precision by means of the adjusting coils. It will impart motion either through direct coupling or belting. One of these in service, operating a three-cylinder pump, is capable of most perfect regulation between very large limits. There are no shocks, the traction on the pulley is regular and constant. Such a pump has taken the place of a steam pump which consumed, according to circumstances, from 30 to 75 kilogrammes of steam per hour, while feeding the boiler with 600 kilogrammes of water. The horse power expense theoretically varies, then, between 180 and 340 kilogrammes of steam. Per contra, the electric motor which supplanted the engine absorbs six amperes at 110 volts, or 660 watts, which costs hardly 10 kilogrammes of steam. The economy is nearly 10 per cent. in coal consumed. Another instance is given where a similar application of electric power has effected a saving of 14 per cent. In addition to this there is a large economy in the item of oil by the electric system, which averages about 87 per cent.

A system of feeders for several boilers actuated by a single motor is suggested. A small reservoir is placed between the pump and the feedpipe running to the several boilers, each of which is fitted with a check valve and an indicator. There is no waste of steam or power, and the whole operation of water feed is made perfectly automatic and thoroughly economical. With no demand on the reservoir, the motor stops and the pump is still.

ELECTRIC LOCOMOTIVE OF 100 HORSE POWER.



ELECTRIC LOCOMOTIVE OF 100 HORSE POWER.

ON THE CONSTITUTION OF THE ELECTRIC SPARK.*

IF a Leyden jar is discharged through metal electrodes, and the spectrum of the spark is examined, it is found that the metallic lines are not confined to the immediate neighborhood of the poles, but are seen sometimes in the center of the spark, several millimeters away from the electrodes, from which they must have been projected with considerable velocity.

It has always seemed to me to be a problem of interest to measure the velocity of projection. A knowledge of it may teach us something concerning the mechanism of electric sparks and, in addition, we may hope to obtain information on some important points in spectrum analysis, which are at present under discussion. Thus, for instance, if the speed with which a molecule is pushed forward into the center of the spark depends on molecular weight, we may separate from each other those lines of the spectrum which belong to different molecular combinations. For many years past I had made various unsuccessful attempts to deal with this problem, when I became acquainted with the elegant method used by Prof. Dixon in some of his recent experiments, in which a photograph is taken on a film fixed to the rim of a rapidly revolving wheel, of which the speed may easily be made sufficiently large to measure velocities of moving luminous particles up to 2,000 $\frac{\text{meters}}{\text{second}}$. This number might be doubled or trebled with improved appliances.

The experiments were conducted by Mr. Gustav Hemsalech, to whose care and skill their success is largely due. Without entering into a detailed description of the apparatus, it will be sufficient to say that the photographs, which I now sub-

* By Prof. Arthur Schuster, F.R.S. (Read before Section A of the British Association at the Toronto meeting.)

on a strip of cloth soaked in polishing powder boiled in water, the cloth being firmly fixed at one end and held at the other in the left hand. The hollow parts are polished by means of cloth pads of various sizes fixed on sticks. These pads must be dipped in the polishing paste when using them. The articles, when well brightened, are washed in water to get rid of the paste and the wool threads, and finally dried in sawdust.

THE GLASGOW CABLE RAILWAY.

AT the beginning of the present year the walls of Glasgow were covered with immense illustrated posters announcing the setting in operation of a district subway of an underground railway, "the only subterranean cable railway in the world, without steam or smoke, having a perfect system of ventilation, permitting of making the circuit of the city in half an hour, and carrying passengers from one station to another in two and a half minutes."

FIG. 1.—INTERIOR VIEW OF ONE OF THE TUNNELS OF THE GLASGOW RAILWAY.

The fact is that Glasgow, like Budapest, imitating cities of larger size, is giving Paris a good example to follow in the possession of a railway that is at present rendering the greatest service to city travel.

A mere glance at a plan of Glasgow will show that the city, inclusive of its outlying wards, is divided in two by a river, the Clyde, which is much deeper than the Seine, and the bed of which is formed principally of sand and gravel. Finally, let us add that, in addition to the difficulties resulting from the watersoaked nature of the ground, there were found pockets of water in old quarries, and it became necessary also to construct retaining work in some abandoned mines that had to be traversed.

The line under consideration is circular, but is not located at the periphery of the city, as such a position would render it perfectly useless. It was desired principally to connect the western quarters, Millhead and Partick, and especially those which, like Govan, are so much the more isolated in that they are on the other side of the port, with the heart of the city and the central station of the railways. The service had to be as frequent as that of tramways, and afford a speed of from 11 to 12 miles an hour, inclusive of stoppages. The extent of the circle which is thus described is about six miles, which is considerable in view of the fact that the establishment of this line was not decided upon until 1890 and that it has been in full operation since the beginning of 1897.

The road is provided with two tracks, each in a separate tunnel, so as to diminish the cubage of the excavation and to facilitate the ventilation by the passage of trains always in the same direction.

These tunnels are cylindrical tubes of brick and concrete or of metal, of 11 ft. internal diameter, separated by a space varying from 30 in. to 6 ft. in width. The metallic rings are made of segments of cast iron provided at the circumference with flanges that permitted of assemblage by bolts, the joints being rendered tight through the interposition of oak. A system of drainage is provided all along the two tunnels in order to carry off the water, which at certain points is raised by pumps. The stations, which are fifteen in number, are sufficient for a length of 6 miles, since this supposes them to be very near each other on an average. Several get their light from the exterior, through glass overhead. Certain of them, in fact, are at such a depth only that the rail is at a level of 13 ft. from the surface of the street. With others, the corresponding distance reaches, as at Buchanan Street, 39 ft. or over. As a general thing, the passengers who descend from the street to the platform by special stairways have to travel a vertical distance of about 19 ft. Electric elevators, however, are in course of construction at Buchanan Street and Saint George's Cross, the two deepest stations. For each station there is a single platform, which is situated between the two tracks and rises to the level of the floor of the cars, according to the excellent English method. It is to be remarked that upon this line, in which gradients have been almost completely avoided save at the double passage of the Clyde, each track presents an incline of $\frac{1}{16}$ at the entrance to the stations and a like one at the exit therefrom.

This is, on the one hand, for facilitating the stoppage of the trains and seconding the action of the brakes, and, on the other, for rendering the starting easier and suppressing all abnormal strain upon the cable.

Before speaking of the latter, of the exploitation and of the rolling stock, let us say a word as to the excavation of the double tunnel. This was established in part only by means of a shield, say for about a third of its length, and where it is now formed of iron segments; but in the sections where it could be made of brick and concrete, the contractors, Messrs. Simpson & Wilson, had to use a great deal of ingenuity in order to contend against moving earth and the influx of water and to protect the buildings and even the railways under which the work had to pass. Sometimes, as with the ground in the vicinity of the Clyde, it was possible to proceed according to the system called "cut and cover," that is to say, to establish a cutting in which were constructed in the open air the invert, the lateral walls and the vault. At least 140 running feet were constructed per month. At the Cowcaddens station the method employed was one that was devised long ago at Glasgow for other work and imitated at Paris for the Sceaux Railway.

This consisted in making an excavation sufficient for constructing the vaults upon a mass of earth performing the role of centerings and then finishing the work subterraneously. The work was complicated in that the running of the surface tramway cars could be interrupted for only a short space of time and at night, and that it was necessary to support a huge water main above the cutting. At certain points the vaults could be constructed in the same way, but the work had to be completed with compressed air and air locks, in effecting a great saving over iron tubing, although the compressed air escaped in large quantities through the earth. Sometimes recourse was had to the iron tunnel, but without compressed air, when impermeable strata were traversed and it was desired to avoid any ramming at the surface. Shields were also employed, and these had the advantage of sustaining the mass of earth during the excavation and the putting in place of the iron segments. Naturally, also, the shield and compressed air were used simultaneously at the different points where the ground was watersoaked—in the crossing of the Clyde, for example. Here, since the depth under the river bed was slight, the compressed air often forced its way through the bed and made a hole therein which it was very difficult to fill up. It became necessary to set up framework in front of the shield, and to regulate the pressure of the air according to the height of the water in the river, etc. Upon the whole, all the difficulties were surmounted with a skill that does honor to the engineers and contractors who brought the work to a successful finish.

We have said that the propulsion is by cable. It is assured by two central 1,500 horse power engines, of which only one is operating. At present, since the traffic is as yet small, only 400 horse power is used. The cables, which run all along the track over vertical sheaves, and are tautened at the extremities by a special apparatus, are 1·3 in. in diameter. Each of them weighs 58 tons. The cars are attached thereto by a grip that can be opened instantaneously. These cars are very long and are mounted upon trucks. They run upon a track of 4 ft. gage. The interior is plain, but sufficiently comfortable. They are lighted by means of electric lamps that take a current from a conductor fixed to the wall of the tunnel. They have a platform at each extremity, with two entrances only, these being sufficient for a population which is capable of "making haste slowly." They have sufficient capacity to seat 42 persons and allow standing room for as many more.

In conclusion we may say that at present there are but eight cars running simultaneously upon each circular track. This, however, gives one train every five minutes. At first, the cars were run from eight o'clock in the morning until eight at night, but the success of the line quickly forced the management to run them from a quarter past seven till a quarter past eleven. It has been recently stated that trains of two cars are soon to be put in service.

The cost of the railway was not so very high, since the total expense of establishment, inclusive of the rolling stock and central power house, was but £1,100,000. —La Nature.

A TUBE TUNNEL UNDER THE SPREE.

A TUNNEL possessed of some interest from a technical point of view—more, perhaps, in connection with the condition of the soil (sand) through which it is being carried than as regards its actual construction—is at present being built under the River Spree, between Stralau and the Treptow Park, where the exhibition was held, and for which purpose it was originally intended. The tube tunnel has a length of about 1,510 feet, the breadth of the river being about 670 feet, the depth on that spot 11 feet, and the bottom of the tunnel some 25 feet lower than the bottom of the river. The inside diameter of the tube is 13 feet, and the tube itself is circular. The tube consists of rings of about 2 feet breadth, made up of nine pieces; these are of pressed steel, and connected by means of bolts. The tunnel tube is surrounded by a layer of cement, the thickness of the steel plate and the protecting cement layer being respectively 10 and 80 millimeters. The permanent road inside the tunnel is also made of concrete. The shield, in which the workmen are, is a tube of somewhat larger dimensions than the tunnel itself; and it is pressed forward by hydraulic pressure, its front end being beveled so as to be better able to cut its way through the soil. The front of the chamber, in which the men work in compressed air, has apertures, which can be closed airtight, through which the soil can be worked and loosened. The working chamber is divided into two compartments; the men in the outer are employed in removing the soil, while the cementing is done in the second. The average progress is some 2 feet to 3 feet per day, although about twice the distance has been compassed when special pressure has been put on. So far everything in connection with the undertaking has worked satisfactorily.—Engineering.

The experiment of double rudders on warships has produced such altogether unsatisfactory results that those now in use will be taken off at once, and no more will be tried. Two rudders, one forward of the other, were put on the gunboats Helena and Wilmington, the remarkably light draught of those vessels giving little room for attaching one good sized rudder, and as these vessels were also designed for maneuvering in narrow river channels, the twin steering expedient was adopted to increase their obedience to the helm. On their sea trials these vessels were found to steer admirably at full speed, but when they dropped to four or five knots, which is deemed a good river rate, the men at the wheel lost all control of them, and they could not be made to respond to the helm. In subsequent trials the forward rudder was fastened straight astern, and immediately it was found that the ship behaved admirably. Orders have therefore gone to New York, where the Helena is in dock, to take off the forward rudder and fill in the hole it occupied, and the Wilmington, which was on the point of sailing for Montevideo, will be sent to the Norfolk yard in a day or two for the same alterations, which will delay her at least twelve days.

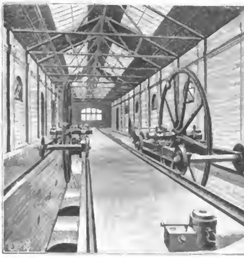


FIG. 2.—MACHINERY FOR TAUTENING THE CABLES.

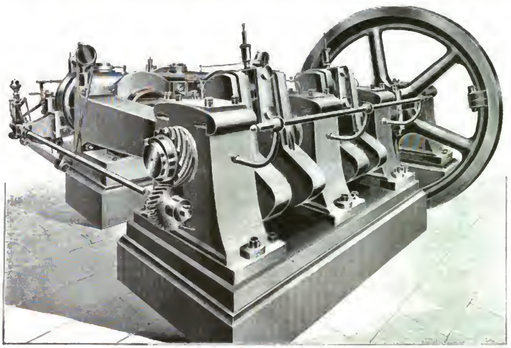
A MODERN GAS POWER PLANT.

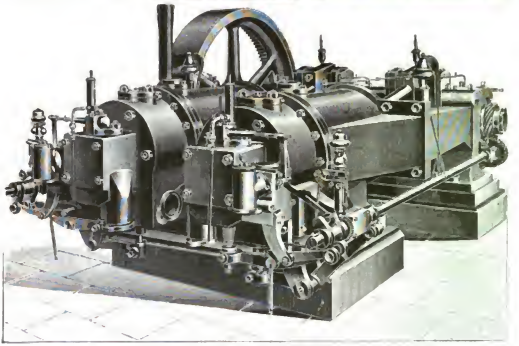
By HORACE ALLEN, C.E.

THE gas generator plant reported on below is of 300 horse power capacity, and works on the Thwaite patent continuous cycle. The apparatus consists of two cylindrical vessels side by side. The fuel is fed into the hopper at the top, and air is supplied by a fan driven from the main engine. The gas, as it leaves the bottom of the second generator, has a high temperature, and is made to heat the incoming air by means of a recuperator apparatus, thus restoring a considerable amount of heat to the generators. From the recuperators the gas passes through a physical purifier to the pressure governor holder, which automatically governs the supply of gas to balance the demand, and from which the gas engine receives its supply. The analyses of the gas, and its thermal value, prove the excellence of the system.

The gas engine, made by Messrs. Hartley & Petyt, is of the duplex type, having two cylinders 16 in. diameter, side by side, the length of the stroke being 2 ft.; and as they are arranged for the Otto cycle, there is one firing stroke every revolution when fully loaded. The speed is 140 revolutions per minute. The charge of gas and air is compressed to about 80 lb. per square inch above the atmosphere, and the pressure of the explosion is about 300 lb. per square inch above the atmosphere. To facilitate the starting of the engine it is necessary to reduce the pressure due to compression; for this purpose a cam is provided which allows a portion of the charge to escape into the exhaust. The design is thoroughly mechanical, and the physical proportions of the machine are adequate for their purpose. There is so little vibration that a penny stood on edge on the cylinder, either lengthwise with the engine or crosswise, was not shaken down. The photograph shows the teeth on the fly wheel into which the pinion of the small starting engine gears; this engine is of the vertical type, having a cylinder 8 in. diameter.

The balancing of the crank has produced very steady turning, the timing valve is simplicity itself, and the best point of firing can be instantly ascertained. The lubrication is on the circulating principle, a small pump effecting this. Both tube and electric ignition gear are applied to the engine. The engine house is covered with a water tank, which feeds the circulating mains of the engine. The hot water is used in the dye vats, so that there is no loss of heat from this source. Another heat loss of ordinary plants is that of the sensible heat of the gases evolved from the gas generators. In the plant under consideration this heat, representing 30 per cent. of the total heat of the fuel, is restored for two purposes, one of which is the drying of the textile materials—an important industrial function—and the other is the restoration of the heat to warm the air used in the gasification process, and for the purpose of increasing its moisture absorbing characteristics; this last development is covered by one of the Thwaite patents.—The Engineer.





ONE HUNDRED AND FORTY HORSE POWER DUPLEX GAS ENGINE.

WORKING AND HARDENING STEEL.

"NEARLY all persons, in writing on the proper method of working steel, lay too much stress on overheating, or what they term 'burning steel.' During my experience, I have found that there are more steel tools destroyed by working too cold, or improperly manipulating on the anvil, than from any other cause. The uninitiated have heard so much about burning steel that they are really afraid to bring a piece of steel to the proper heat for forging purposes. I have often seen the novice working steel down to a black heat under the steam hammer, not only destroying the structure of the steel, but the hammer dies also.

"A man working at the fire next to mine continually had complaints coming to him about his tools being burnt, in fact, his tools would come back broken off about one half inch from the point, showing a coarse, black structure, similar to a piece of overheated or disintegrated steel. The poor fellow was hammering away on cold steel all day long. Finally he said to me, 'Why is it that they all tell me that my tools are all burnt, when I work them at a much lower heat than you do; yours do not break short, mine do.' I told him that his tools were not burnt, but improperly manipulated on the anvil, i. e., worked too cold, and not properly hardened after being brought to the proper shape. He replied: 'If I were to bring steel to the heat you do, they would all break off about three-fourths inch from the point.' He then showed me many of his tools broken off as described. I examined the tools which were not broken, and which had given good service after the last dressing, and found that nearly all of them had been reinforced about three-fourths inch back from the point; this compression is almost imperceptible to the naked eye, but can easily be felt by passing this part of the tool between the thumb and finger. I informed him that the next time he dressed those tools they would break at the point mentioned as soon as put in service, and show a dark, coarse structure, similar to overheated steel; the men using the tools would upbraid him for burning the tools.

"The cause of so many tools breaking at this point is improper hardening, or rather, the hardening and tempering are done too quickly, leaving a hard and soft section in conjunction with each other; consequently, the hard section is driven into the soft, displacing the

original structure at this point and making it unfit for any purpose; unless the piece is cut off at this point when dressed, it is liable to break off by dropping on the floor. To avoid this, heat your steel sufficiently to harden the whole length of the taper point, and retain heat enough in the body of the tool to draw the temper slowly; if the tempering is done too rapidly, or the blue color allowed to run too fast, then submerge in water to stop its further progress. At the junction of the bright and blue color the hard and soft section is formed with the above results. The color should run very slowly, so as not to produce any sudden change in the structure of the steel when tempering. The above articles refer to tools that are subject to impact force or heavy blows, such as stone cutter's tools, chipping chisels, etc.

"Improper manipulation in forging causes many imperfections in steel tools. When the piece to be forged is of uneven shape, the force of the blow from the hammer must be governed by the section of the piece it is shaping. In nine cases out of ten, where chisels are found cracked on the corner, it is caused by striking the edge of the chisel when too cold, causing compression to take place a little below the surface that received the blow. Some persons claim that these cracks are caused by uneven heating before hardening; others call them 'fire cracks.' Admitting the fact that uneven heating will produce similar flaws to those referred to, my experience has taught me that they are mostly caused by improper hammering on the anvil.

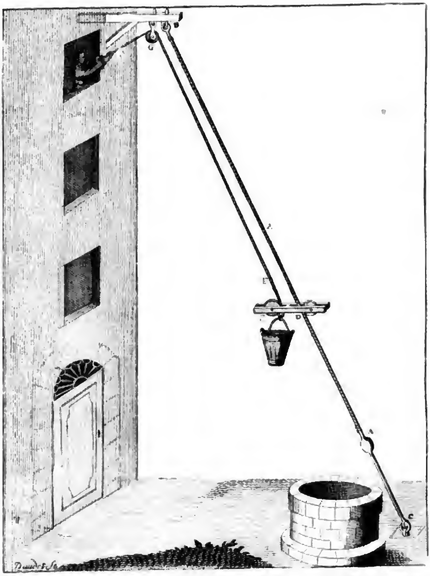
"Steel tools that have to be finished in the lathe or planer, such as taps, dies, milling tools, etc., great care should be taken in forging. If the steel has to be reduced from a large to a small section, bring the steel to a bright red heat for the purpose. Every blow struck should affect the piece from surface to center; if the piece is worked too cold, the blows affect the piece only partially through its section, causing two structures in the same piece; consequently, the uneven structure will maintain itself through all the operations in finishing the tool, and when completed it will not give satisfaction. This class of tools, after being finished, will come back to the smith to be hardened.

"The conditions in heating steel for forging purposes and heating finished tools for hardening are vastly different: in the latter case great care must be taken in [illegible] whole piece to be hardened should be [illegible] and uniformly over the whole piece, as [illegible] harden at a lower heat than others. The [illegible]now, before heating a costly tool, the necessary heat, when plunged into water, to produce the hardness required; overheating in this case means destruction to a costly tool. If it is a complicated tool, having delicate projections, baths should be prepared, which are not as good conductors of heat as the bath for ordinary purposes, as the slender projections will cool much more rapidly than the body of the piece. Oil is often used for this purpose, but any liquid will answer that will give the thin projections sufficient time to cool, at the same time producing the hardness required. We should always bear in mind that it is the time it takes a piece of steel to cool that determines its hardness, other conditions being equal."—President Wren, at Convention of National Railroad Master Blacksmiths' Association.

VERY CONVENIENT MACHINE FOR DRAWING WATER FROM A WELL REMOTE FROM THE HOUSE THROUGH A FIRST OR SECOND STORY WINDOW.

AFTER stretching the rope, A, as tightly as possible from the point, A, beneath the window, to the point, C, near the well, and after passing the rope over the pulley, D, so that the latter can roll freely up and down, the rope, F, that carries the bucket is passed over the pulley, E, and then over the pulley, G.

In this way, in measure as one slackens the rope, F, the bucket, through the pulleys, D and E, that follow it, will descend diagonally from the window to a point above the well, where the pulley, D, will meet with a knot, A, in the rope, and will stop there along with the pulley, E. Then, in continuing to slacken the rope, F, the bucket will be made to enter the well, into which it will descend perpendicularly in order to draw up water therefrom. Upon the rope, F, being pulled after the bucket has been filled, the latter will ascend perpendicularly from the bottom of the well to the knot, A, and then diagonally, along with the pulleys, D and E, from the knot up to the window.—From Recueil d'Ouvrages Curieux de Mathematique et de Mécanique, 1733.



VERY CONVENIENT MACHINE FOR DRAWING WATER FROM A WELL REMOTE FROM THE HOUSE THROUGH THE WINDOW OF THE FIRST OR SECOND STORY.

IN tearing up a siding on the Straitsville Division of the Baltimore and Ohio Railroad, the other day, the section men discovered that several of the rails had been made in 1863. Subsequent investigation revealed the fact that these rails were part of a lot that were bought in England during the war, at a cost of $125 per ton in gold. The rails were still in very fair condition, and for light motive power might last ten years longer.

KEITH'S AUTOMATIC LIQUID ELEVATOR.

AT the recent Brewers' Exhibition, in London, a new device for forcing beer to the delivery faucet was shown. This device is Keith's automatic liquid elevator, which has been successfully applied to the raising of beer under pressure, as opposed to pumping by the so-called "beer engines." It is stated that the old-fashioned method of drawing beer has one great disadvantage—the abstraction of the natural carbonic acid gas. In Keith's apparatus the beer is forced out of the barrels by compressed air supplied by a pump actuated by water pressure derived from the ordinary mains. By this means it is claimed the air simply acts as a weight, and is prevented from coming into direct contact with the beer by the layer of carbonic acid gas on the surface, CO_2 having a greater specific gravity than air.

The apparatus illustrated herewith is placed in a cellar or basement and connected to the ordinary service water pipe on the one hand and to the top of beer or other casks or closed vessels on the other hand. This compact little engine consists of three main parts, viz.: (1) The water cylinder, A; (2) the air pump, B; (3) the automatic governing valve, D. The water cylinder has a positive valve motion, is connected to the water main at H, and exhausts at K, the governing valve, D, being connected to the water pressure inlet. The air pump, B, is double acting and connected direct to the water cylinder, A, but owing to the open air space between them, it is impossible for any water to get into or near the air pump. The air pump valve box, C, is separate and can be detached by merely unscrewing one nut, each valve being accessible in a moment. The air delivery pipe, F, is preferably connected to the air receiver, which again supplies the air pipes leading into the top of the barrels or other closed vessels, or these can be directly supplied from the air pump, B, and the air receiver can be dispensed with. The governing valve, D, is operated by the air pressure and is exceedingly sensitive; when the pressure reaches the required point, it automatically shuts off the water from the cylinder, and so stops the motor. When the air pressure falls, however slightly, owing to liquid being drawn, the valve, D, instantly opens and the engine starts working until the pressure again reaches the normal. This controlling valve, D, is entirely new in principle and works most efficiently, and in quite a different manner from some forms of regulating valves, which generally require from one pound to three pounds variation of air pressure to move them. The working air pressure can be readily adjusted to suit circumstances by moving the sliding weight, G. The makers of this apparatus are the Water Motor and Automatic Liquid Elevator Company, Limited, Farringdon Street, London.—Engineer.

KEITH'S AUTOMATIC LIQUID ELEVATOR.

THE EARLY HISTORY OF CAST IRON PIPE.

AT one of the meetings of the New England Water Works Association, Mr. Jesse Garrett, of Philadelphia, dealt with the history of the manufacture of cast iron pipe, from which the Bulletin has culled the following:

Cast iron was known to Holland in the thirteenth century, and stoves were cast at Elass in 1400. But tradition has it, which an ancient Roman writer records, that the temple of the "Great Mother," at Sparta, is said to have been built by Theodorus, who first discovered the art of casting and making statues in iron. All this is necessarily vague, a condition which suggests a quotation from Dr. Greene, of the Boston Historical Society, in reference to the present disturbance of King's Chapel burying ground for the subway human conduit. "It is so full of bones and remains that I do not believe you could dig down to the depth of much more than an inch without turning up the dust of ancient worthies." The application is this, that in the dust of these "ancient worthies" it is impossible to verify the individual instance. As with the metal itself, so its discovery in the form of cast iron was an accident which occurred at one of the early iron works in the Rhine provinces, where a part of the "running" one day was found to be of different texture, and it was a problem for some time what to do with the strange stuff.

The first blast furnaces appeared in the Thuringian Mountains, which were almost identical in principle with the present furnaces, with the exception that hand or treadmill bellows were used for the blast, from which the present mechanical blowers are an evolution. In 1377 the first cast iron gun was cast in Erfurt, and the famous Krupp was casting guns in 1818, so that it appears iron was mostly used for destructive and not Samaritan purposes through many centuries of its history. In 1685 the first cast iron pipes were used for the water service of Versailles, followed by screwed and flanged pipes. In 1708 the Quaker, Darby, patented the system of box casting, and in the following year started the famous Coalbrookdale foundry, which, in 1780, turned out the first cast iron bridge. The first casting in the United States is said to have been made at Lynn, Mass., a cast iron pot, which was exhibited at the World's Fair at Chicago.

In the region of Alba Longa, buried by the volcanic eruption which drove the Albans to the present site of Rome, no trace of iron is found, and its absence is still notable in the archaic tombs of Rome. The metal for their implements, of whatever kind, was of bronze, and the early Roman religious sentiment shows such an abhorrence of iron as to make it a profane innovation to use it in almost any form, especially in and around their sacred temples. This superstition continued after the Christian era, even down to the fall of the empire. In their religious rites, if iron had in any way approached a temple or shrine, sacrifices were instituted to expatiate the profanation, so that we can hardly wonder that their attention was not turned to it as a substitute for lead pipe. When iron tools came to be used for engraving, and were so employed on certain altar inscriptions, penitential sacrifices were afterward offered by slaying a cow or a sheep on the altar. Bronze plows were used long after the introduction of iron plows. The high priests of Rome would not shave or have the hair cut with iron instruments.

The first mention of iron pipes I find was in an elaborate system built at Marli, near Paris, and set to work in 1682, costing $1,500,000. The account says: "They drew the water by short suction pipes from the River Seine, and forced it through iron pipes up the hill. They climbed to a height of 533 feet by a series of reservoirs and pumps, but this system came to be known as a 'monument of ignorance,'" probably after cast iron established confidence as a pressure pipe. Agricola makes no mention of cast iron pipes, although he shows three-legged pots of cast iron. Ramelli, about the same period, describes a hand mill of a portable character, whose casing, he says, is made of iron, and its form and ornamentation are such that there is little doubt it was made of cast iron.

Peter Maurice, a German engineer, in 1582 erected, under the arches of London Bridge, 16 pumps, 7 inches in diameter and 30 inches stroke, driven by a water wheel, and these were of cast iron, flanged at their lower end, bolted to a valve chest.

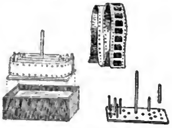
In 1835 it was estimated that over 1,000 miles of iron pipe were in use in the various systems of London water works, the first iron pipes having been laid 1746. Later on we find that cast iron pipes, 9 feet in length and 15 inches in diameter, with ball and socket flexible joints, were laid by James Watt across the Clyde for the conveyance of water to Glasgow, and another of the same size in 1818, and a little later on another of similar construction of 36 inches diameter.

Contemporary with the history of cast iron pipes in America is Peter Adams, a moulder and core maker, born in Millville, N. J., in the year 1823. His grandfather, James Adams, was a soldier in the revolutionary war. His father, Mark Adams, was born in 1788, and was a moulder and core maker at Weymouth, N. J., where he was engaged on the first cast iron pipes made for the city of Philadelphia, from designs and under the instruction and inspection of Frederic Graff, first, who was the then engineer of the Philadelphia water works, and father of the later Graff, who succeeded him in office. The first pipes made for Philadelphia were for the pumping main, of 18 inches diameter, delivering into the reservoir, the distribution still continuing throughout the city through wooden pipes. These pipes were cast direct from the melting of native bog ore, and the process was about as follows. In the beds where pigs were usually run were moulds for pipe, which tapped the flow from the furnace until one pipe was complete, then on to another mould, and so continuing for as many pipes as were planned for that pouring, using the surplus from the pipes for pigs as usual. The proprietor of these furnaces at Weymouth was a Mr. Richards, a native of the city of Philadelphia and its mayor at that time. After this, Mr. Adams thinks that the first pipe made at Millville, N. J., was about the year 1830, the inspector for which, under Mr. Graff, he remembers as one Louis Ort, who "was a good fellow enough, but inclined to be very particular unless he got one or two glasses of whisky before beginning his daily inspection, in which case it was very seldom that he would reject a good pipe."

The first pipes made at Millville, as at Weymouth, were from the product of the bog ore furnaces, and at that time, of course, cast upon their sides, a series of gates, six or eight in number, used for running the iron from the furnace into the pipe moulds, which, at the proper time, were cut off and the flow of iron continued to another series, or to the pigs, as the case might be. As time went on, and the demand for cast iron pipes increased, and sentiment ripened against using the melt direct from the ore, the proprietor of the Millville Works, David Wood, designed and constructed special foundries for their manufacture. The original proprietor of the Millville Iron Works, as before stated, was David Wood, a brother of R. D. Wood, who succeeded him and who afterward added to his pipe works from time to time until their production became the largest in the country.

DEVELOPER FOR FILMS.

ONE of the inconveniences of strips of films is that connected with development. It is either necessary to cut them in order to allow them to enter the tray, or else it requires great experience to cause them to pass through the bath properly. The small developer which we figure herewith solves the difficulty. It suffices to fix the strips around pegs, the emulsioned side outward,



DEVELOPING DEVICE FOR FILMS.

and to immerse the whole in the gutta percha trough containing the bath.—Le Monde Illustré.

PHOTOGRAPHIC WASTE MATERIAL AND WHAT TO DO WITH IT.*

IT would take but a sorry detective to discover the presence of an amateur photographer in any household his calling might lead him to be interested in. Every possessor of a camera is also the owner of vast treasure, in the way of glass, and his dwelling may be likened to a cross between a marine store and a crockery warehouse after it has been invaded by the proverbial member of the bovine species.

His friend looks in on Sunday evening and finds him piously engaged with a biblical treatise, a state of things which is sadly belied by scraps of P. O. P. scattered on the floor, and other telltale indications.

Undoubtedly spoiled negatives form the greatest part of the unsalable matter which litters his abode. I shall, therefore, consider these first. The uses to which a ruined negative may be put are manifold. Cut down to 3¼ inches square and the films cleaned off, they make excellent cover glasses for lantern slides. Another use for them in the same popular branch of photography is the following: If, during development, you see that your negative is spoiled through uneven density, excessive overexposure, or what not, expose it to the light and allow it to blacken all over. Now sealing-wax a needle to a penholder, and by means of this little tool you can easily manufacture diagram slides from your darkened film (white lines on black ground).

Take a spoiled negative, dissolve out all the silver with a solution of potassium ferridcyanide and hypo. Rinse, dry, rub with sandpaper, and you will have a splendid substitute for ground glass.

Remove the silver in a similar manner from another negative, but this time wash thoroughly. Squeegee down on this a print, and an opaline will be your reward. From such an opaline, by cementing on a few more glasses, a tasteful letterweight may soon be made. Another way in which very thin negatives may be utilized appeared in these columns some months ago. It is this: Bleach them in bichloride of mercury, back them with black paper, and positives will result. Old negatives also make good trimming boards, the film preventing a rapid blunting of the knife, and they may be successfully used as mounting tables. Clean off the films, polish with French chalk, and squeegee your prints thereto. When dry they may be removed and will have a fine enameled, if hardly artistic, appearance. Many other uses for them may also be found if the amateur is at all ingenious.

Users of pyro, instead of throwing the old developer away, should keep some of it and allow it to oxidize. A thin negative, if immersed in this for a few minutes, will be stained a deep yellow all over, and its printing quality will be much improved.

Old hypo baths should be saved, and, when a sufficient quantity of silver is thought to be in solution, reduced to recover the metal.

Printing paper of any sort is another great source of waste, especially to the inexperienced photographer. Prints are too dark or not dark enough to successfully undergo the subsequent operations. Spoiled material of this kind, however, is not without its uses in photography. Those who swear by that unreliable combination, yclept the "combined bath," will find that scraps of P. O. P., or any silver paper, are necessary to start the toning action.

Spoiled matt surface P. O. P., bromide paper, or platinotype should be allowed to blacken all over. Here we have a dead black surface useful for many purposes. A leak in the bellows when out in the field; repair it temporarily by moistening a piece of matt P. O. P. and sticking it on; the gelatine will cause it to adhere. These papers may also be used to back plates, platinotypes, of course, requiring some adhesive mixture to make them stick.

In every photographer's possession there will be found a small percentage of stained prints. Instead of throwing these away, you may often turn them to good account in the following manner: Take a large piece of cardboard, some mountant and the prints. Now proceed to tastefully mount them so that the corners of some overlap, arranging in every case to hide the stain. If you have gone properly to work, you will have an artistic mosaic. Now wash round with Indian ink, or paint a border of leaves, and the whole thing will form a very nice birthday gift to a friend. Little "tit bits" trimmed from a stained print are also very useful to mount on correspondence or invitation cards.

Keep the stiff bits of cardboard between which your printing paper is packed. They are useful in many ways—from opaque cards in the dark slide to partitions between negatives in the storing boxes.

Plate boxes are useful to store negatives in. Before doing this, however, each negative should be incased in a paper envelope. Hundreds of these latter may be quickly manufactured; cut out the pattern and get a juvenile to paste them for you at so much a score.

In short, nearly every waste product has its uses, even the brown paper in which your camera was packed. This makes a good paste down tint for mounting platinotypes upon.

There are, I know, a few amateurs with whom money is a plentiful commodity, and these can afford to be wasteful; but the great majority have to be careful with their cash, and to these economy means everything. Then there is the pleasure of knowing that you have obtained the maximum of success with the minimum of waste.

* By R. A. Hanolin, in the Photographic News.

CONVERTING SLUDGE INTO FUEL.

WORKMEN are now engaged at Rotherhithe in erecting machinery which, when in proper running order, is expected to revolutionize the methods of disposing of the more than two million tons of sludge that the main drainage committee of the County Council have to dispose of anually, says the Pall Mall Gazette. Before three months have passed, the municipal authorities of most of the large towns in the United Kingdom, together with the experts on matters connected with sanitation, are to be invited to witness the "trial trip" of the machinery, and if the results of experiments already made on a comparatively small scale are borne out in the greater experiment that is to be made, it is said that one of the greatest difficulties with which the authorities of most cities have to contend will disappear. Instead of a costly work, which it undoubtedly is at present, the doing away with the sludge will be converted into a profitable undertaking for the County Council.

Some years ago it was believed that the sludge of London possessed great value as a fertilizer, but those whose business it was to attend to its disposal found it quite impossible to get it taken up in sufficient quantities to be of any use to the County Council; and despite the enormous cost for steamers and their maintenance, it was found that to take it out and dump it into the North Sea fifty miles from shore was in the end the least expensive and most expeditious method of getting rid of the refuse.

The London County Council maintains a fleet of six sludge vessels, each capable of carrying a load of close upon one thousand tons to sea. The total number of trips made by these steamers last year was 2,176, and the cost of working the vessels came to more than £27,473. They are insured for £120,000, at an annual premium of £2,400. These expenses the new arrangement is expected to save, and at the same time the belief is that the County Council will be left in possession of an amount of fuel estimated at anything up to 700,000 tons per annum.

Leaving beaten tracks, investigators have for some time past been experimenting to convert the sludge into fuel, and the results obtained with comparatively moderate quantities, it is said, have led those interested to believe that all of the millions of tons annually dumped into the sea can be made, at virtually no cost, into good burning furnace fuel. When these experiments were completed those interested gave orders for the setting up of a large plant in Rotherhithe, and the work is now rapidly approaching completion. At the public trial of this machinery some half a hundred tons of the sludge brought from Barking is to be converted into fuel blocks by what is called the "Henry" process of sludge treatment. This process, briefly described, is as follows: The sludge, which, taken in large quantities, contains about 90 per cent. of moisture, would be treated by Hencke-Cunliffe machinery. It is pumped straight into machinery consisting first of two enormous hollow cylinders. These cylinders are heated internally by hot air, and being close-geared and revolving slowly, they are said to film the sludge on their face at about the thickness of a sheet of blotting paper. By far the greater part of the moisture is evaporated at one revolution of the big cylinders, and the nearly dried sludge is automatically scraped off, and falls into jacketed pans, which, like the cylinders, are heated by hot air and fitted with slowly revolving sweeps that stir and carry the sludge along until the whole of the acquired amount of moisture is evaporated. Then the sludge is automatically discharged upon machinery that presses it into fuel blocks ready for consumption in furnaces.

LEFTOMANIA.

ABSENT-MINDEDNESS would seem to be on the increase, says the Humanitarian. This is a disease not, indeed, to be found described in the pages of the British Medical Journal, but one, nevertheless, clearly defined under our present social conditions. To some extent kleptomania, with which we are all conversant, is its complement. The Great Eastern Railway auction is a wholesale example of the extent of the disease. Two thousand umbrellas, half that number of walking sticks, 800 hats, bicycles, perambulators, and feather beds were unintentionally abandoned by their owners during the past twelve months. Leftomania is recognized at all theaters, and due provision is made for the failing.

ENGINEERING NOTES.

For some years past a solitary dining car has been running on the Rohil Khand and Kumaon Railway. The example has now been followed on another line, a dining car having been recently put on the Bombay-Calcutta limited mail.

The Paris correspondent of The Times gives particulars of the trial trip at Mantes of the electric locomotive devised by M. Heilmann. The train was composed of twelve carriages and a luggage van, and carried 250 persons, and weighed about 150 tons. The object of the trip was not to make a trial of speed, and the train journeyed at the rate of only 18 miles an hour. The experiment seems, however, to have been considered a great success, and testimony is borne to the ease and regularity of the movement of the train. Great things are hoped from this invention, no less than the conveying of a train weighing 300 tons at a speed of 62 miles an hour being looked forward to.

In the latest annual report of the Chief of the Bureau of Steam Engineering the following note occurs: "The improvement in machine tools in the last twenty years has been so great that private builders who are at all enterprising throw away old tools, although in good condition, to give room for the latest and best. One large firm, with what was considered one of the best plants in the country, recently broke up good tools valued at $40,000, because they were becoming antiquated, and expended $200,000 for new ones of the latest pattern to replace them." It is by keeping themselves entirely up to date that the Americans are able to produce machinery of all sorts at a greater rate and more economically than other nations. The last sentence, coming as it does from The Engineer, of London, is significant.

Various schemes have been proposed for the last quarter century for the use of the ruins of the Cour des Comptes, on the Quai d'Orsay, in Paris, so long a memorial of the "Commune," and at one time it was arranged to convert the ruins into an imitation of the South Kensington Museum. But utilitarianism has finally gained the prize from decorative art. The Chamber has agreed, says Architecture and Building, to a proposition for the concession of the block to the Compagnie d'Orleans, in order to erect on the site a terminus which will be more central than the present building on the Boulevard Montparnasse. The interests of the International Exhibition of 1900 must have had an effect on the voting, for some years ago a railway terminus in such a position would not have been tolerated.

J. J. Holtzapffel, in a paper recently read before the Society of Arts on the uses of the sand blast, alluded especially to the value of the process in sharpening files and the superiority of the process, the sand-blasted file doing twice the work of the ordinary file in the same time, this superiority being now so fully recognized that 240,000 dozen files are so prepared in Sheffield yearly. They can also when worn be resharpened over and over again, without grinding out the old marks, for about 2½ per cent. of their value. He also spoke of the efficacy of the blast in removing every trace of scale from iron castings, so that the finest tools may be applied at once to the metal, and of its usefulness in refacing grindstones and emery wheels, cleansing bicycle tube surfaces before brazing, granulating or frosting electric plate, gilding metals, gold and silversmith's work, and jewelry, and many other purposes suggestive of a widely extended field for the sand blast in metallurgy.

Some interesting statistics of the world's output of steel were laid before the last annual meeting of the German Iron and Steel Institute, from which it appears that the production of steel ingots during the past three years was as follows:

	1894.	1895.	1896.
United States.	4,420,000	6,143,000	5,000,000
Germany	3,781,000	4,100,000	4,900,000
United Kingdom. ...	3,060,000	3,312,000	4,200,000
France	818,000	876,000	1,128,000
Russia	605,000	785,000	900,000
Austria-Hungary ...	649,000	782,000	862,000
Belgium	445,000	455,000	598,000
Sweden	167,000	194,000	250,000
Spain	70,000	65,000	105,000
Italy	65,000	80,000	60,000
Canada	40,000	40,000	40,000
Totals	14,274,000	16,738,000	18,650,000

In addition to the above, about 230,000 tons of crucible steel are manufactured, the United Kingdom producing about 100,000 tons, the United States about 70,000 tons, and other countries the balance, says The Colliery Guardian.

Some of the engineering difficulties encountered by those engaged in the construction of railways in Africa are pointed out by a correspondent of The London News, the principal one being the lack of water. Thus, at Wadi Halfa, the engineers' headquarters in the Soudan, some 12,000 gallons are daily collected and thence sent forth to the various stations, the most distant being 60 or 70 miles. The water is carried in iron tanks, each tank filling a truck. Every train that starts from Halfa laden with materials, such as rails, sleepers and other gear, has no less than fifteen of these trucks, which, by the exigencies of the situation, are loaded with water alone. The quantity of water thus conveyed, large though it is, suffices only for drinking purposes. On this account it has been considered a matter of great good fortune that the officers in charge of this work have now discovered that by boring at a point in the desert some 75 miles or so out from Halfa water may be obtained at a depth of about 50 ft. As might be expected, much speculation has been aroused by this flow of water more than 1,000 ft. above the level of the Nile. Among the many theories on this subject, that which obtains most favor among geological and other experts is this, namely, the existence under the Nubian desert, beneath a flooring of rock of varying thickness, of an immense reservoir containing a practically unlimited supply, and that digging at any one point would be rewarded with success, the question being merely one of depth. Another attempt is to be made to find water 50 miles further on.

ELECTRICAL NOTES.

It may not be generally known that in the city of Brussels, in Belgium, a system of electrically operated clocks was installed in April, 1857, at which time 100 clocks were installed, using the Nolet system. With some modifications, says The Electrical World, they have been in operation ever since then.

An exchange reports that in an examination that was made of some "electric belts" sold by a street fakir, it was found that beneath a strip of gauze was a layer of dry mustard. When the wearer perspired a little, the mustard was moistened and set up a burning sensation, and the deluded victim believed a current of electricity was passing through him.

An isolated electric plant was recently installed in a large tea firing or curing establishment in Yokohama. This establishment employs 2,000 people, who clean and sort the tea by native fan blowing and sifting machinery, after which it is taken to the firing rooms, containing 1,500 pots, set in brickwork and heated by a slow fire, the tea being stirred continuously by the coolie who attends each pot, the work going on day and night during the busy season.

United States Consul Child, at Hankow, has informed the State Department that an electric light plant has been established in that city, which is the capital of the most exclusive and hostile province in China. It was in this province that the Chinese a few years since refused to allow telegraph poles to be erected, and the missionaries have encountered there more opposition than at any other place in China. The public buildings have adopted the new light, and all prejudice is giving way to the new invention.

One of the many remarkable things in Australia is the overland telegraph from Port Darwin to the south of the continent, which was completed in 1872, says The Electrical Review. Almost the whole 2,000 miles of its length were through uninhabited country—much of it a waterless desert. The wooden poles were prepared at the nearest available places, but some had to be carried 350 miles, while the iron poles were taken an average distance of 400 miles by land. Over 2,000 tons of material had to be carried into the interior, and the total cost was $1,850,000.

A charter was granted by the State Department of Pennsylvania on November 8 to the Washington, Westminster & Gettysburg Electric Railway Company, which will build a line fourteen miles long, from Gettysburg to the State line. This is the company which intends to build a line to the national capital. The capital stock is $100,000, and the officers are: President, James B. Colgrove, Washington; directors: Samuel S. Bushman, Charles A. Trastel, and Henry C. Little, Gettysburg; Henry A. Cady, Washington; Charles H. Duttera and John A. Shore, Littlestown.

The lighting plant of the new limited trains of the Lake Shore & Michigan Southern Railway consist of a 30 horse power compound Westinghouse engine, with a 7 by 7½ inch cylinder giving 400 revolutions with steam at 80 or 90 pounds. The engine is direct connected to an 18 kilowatt Westinghouse compound multipolar generator of 120 volts, operating in all about 300 lamps of from 12 to 20 candle power each. The outfit is placed at the forward end of the luggage car, steam being supplied from the locomotive by a system of pipes and flexible rubber couplings. The cars are connected by a flexible plug coupling, and a similar plug is arranged to supply current from the city circuits at stations where a change of engine is necessary.

Three-phase current transmitted from the water power plants of Sacramento and San Joaquin Rivers is being used to operate milling machinery in Fresno, Cal. In the case of the Sperry Flour Mill a 150 kilowatt General Electric synchronous motor, running at 600 revolutions per minute, is operating the various machines, says Engineering News. In another mill, which is the largest flour mill in the United States using electricity as a motive power, three General Electric three-phase induction motors of 75, 30 and 20 horse power are belted to the mills, cleaners, etc. These motors are provided with recording meters and are run only when the machines to which they are connected are needed, thus effecting a saving of about 15 per cent. in power.

According to The Pall Mall Gazette, the movement toward an introduction of automobile cabs and omnibuses has reached Berlin, and soon a number will be in full action there. Some of the leading men of the electric establishments, among others Mr. Rathenau, the director of the Berlin Electric Works; Mr. Borsig, head of the largest locomotive building establishment; and Colonel Budde, the chief of the railway department in the "Genaistal" of the Prussian army, have founded a company for motor cabs and omnibuses in the great towns of Germany, and they will begin their action at once in Berlin if the president of police does not put a veto in their way. The Berlin pavement, mostly macadam in the principal thoroughfares, is well fitted for motor cabs, and there is every hope of success for such a company.

Nearly every electric road has one or more cars that are slow. They may be of a comparatively primitive type, as far as the motors are concerned, but the trouble can usually be cured by rewinding the armatures and fields, or by a rearrangement of the controlling apparatus, says The Electrical World. The presence of a single slow car will make itself felt very quickly over the whole line upon which it runs; and the quicker such a car is sent to the shop and "speeded up," the better will it be for the interests of the company operating it. On one road it has been the custom to run such cars only when the traffic was heaviest, probably with the idea that as the cars could not travel fast at such times, the slow car would not cause much trouble. The reverse of this was found to be the case. The slow car was slow in getting up to speed after stops, and caused great delay by that action. These cars are now operated only at night, when the motormen are naturally inclined to wild running. The slowness of the car acts as a check in this direction. Thus some use is made of the slow cars, but in spite of this they are being put into the shop to have motors rewound as fast as possible.

MISCELLANEOUS NOTES.

France has 83,163 public schools, an increase of 223 within a year; 15,969 of them are under clerical control. The number of teachers is 151,563, the number of pupils 4,580,183.

The management of French state railways has obtained permission of the minister of railways for the construction and reconstruction of a number of railway passenger carriages in which all parts formerly manufactured of brass, copper and iron, with the exception of axles, wheels, bearings, springs, brake gear and couplings, shall be made of aluminum. The weight of a coach with these fittings is one and a half tons less than that of an old style of carriage, and as an ordinary train in France consists of twenty coaches, says Aluminum and Electrolysis, the weight of the train would be reduced by thirty tons, which would mean a considerable saving in working expenses.

The seat of the Japanese matting industry is the town of Sa'kai, about eight miles south of Osaka, and having a population of 4,800. According to a consular report, the rugs are made principally of jute. The number of people employed in the manufacture is about 9,600, mostly children, girls and boys between seven and sixteen years old. There are 2,400 looms in 800 houses, giving an average of three looms to each house, and each loom is attended by four persons. The warps of the rugs are of cotton, but the weft is thick jute yarn, and the filling thin jute yarn. The designs are mostly Turkish and imitated Persian. The price ranges from 4 to 6 cents per square foot, according to the quantity of material used. When the weavers are fully employed in filling orders, they can turn out 1,800 square yards daily. The yarn used in this manufacture is principally imported from Calcutta.

The lack of efficiency in the ordinary belts is due principally to the air cushions between the belt and pulley, causing slippage. In the pneumatic pulley this air is entirely eliminated by means of perforations all around the face of the pulley. These perforations are regularly placed in rows parallel to the axis, the perpendicular positions of the perforations of each row alternating with those of the next. The belt closely grips the face of the pulley and operates, therefore, without the loss attending pulleys permitting an air cushion between the belt and the face. The use of this pulley, it is claimed, enables the use of a smaller and looser belt, owing to the elimination of nearly all slip, which, with the ordinary pulley, is said to be equivalent to a loss of about 10 per cent. in power. A more uniform speed can be obtained between the driver and driving element, which is an important feature in high speed work. Less tension on the belt means less oil in the bearings, and smaller belts mean smaller first cost.

The use of salt water by the New York fire department is again being discussed by a commission made up of Fire Commissioner Sheffield, Chief Bonner and Foster Crowell, M. Am. Soc. C. E., says Engineering News. Boston already has pipes laid for bringing in sea water for use in extinguishing fires, and Buffalo, Cleveland, Detroit and Milwaukee can use water directly from the lakes in similar cases of emergency. The plan is approved by the insurance companies of New York, and one prominent insurance officer says that a reduction of 5 per cent. in insurance rates would be possible on a line of 10 in. pipes connecting with the North River, or within 500 ft. of a fire unit connected with these pipes. Such a pipe system would vastly extend the usefulness of fireboats by making them effective at long distances from the shore line. The saving in water and damage by fire would more than offset the first cost. As showing the value of the property to be protected, the statement is made that the aggregate value of buildings and property between Chambers Street and Fourteenth Street is at least $500,000,000.

The Boston Transcript says: "Comparisons between the fire in London recently and the conflagration that swept the city in 1666 are natural at first glance, but in reality there is not the slightest resemblance between the two. The recent fire was diminutive in its proportions as compared with what will always be known in history as 'the great fire of London.' The conflagration which began September 2, 1666, and raged for four days, swept over 436 acres, destroyed fully 100 churches and public buildings and 13,200 dwellings. It rendered 200,000 people homeless. A considerable section of the city burned over was practically a survival of medieval London, of dark and narrow lanes and houses that simply stood because they had got into 'the habit of living.' The conflagration was, in fact, a purification by fire. The recent fire was confined to a few acres in the business center of London. The property loss, taking into consideration the scarcity of money two centuries ago, was not as large in the late fire as in 1666, nor are any considerable number of people rendered homeless. The buildings destroyed were business blocks. While some of these structures had been built or modernized within the last fifteen years, more of the blocks resembled the older style of business buildings wiped out by our own fire of 1872, with the addition of a frowsy dinginess of aspect due to the foggy and grime-spreading atmosphere of London."

An account of the organization of beet sugar factories in Germany, in the Consular Reports for November, is interesting as giving an example of the successful application of the co-operative principle. Out of the 399 factories now in operation, nearly half are stock companies, in which the majority of the shareholders are beet growers. These include not only most of the largest factories, but also the most prosperous.—An abstract of the Mexican Annual Statistician for 1895, just published, shows the population of the republic to be 12,578,861, and the surplus revenue nearly two million dollars (silver). There are 24 museums, 69 libraries, with 512,329 volumes; 30 scientific societies, and 454 periodical publications, including 41 dailies and 185 weeklies.—From an interesting description of a visit to the great salt wells in the province of Sze-Chuen, in Central China, we learn that the majority of the wells are from two to three thousand feet deep, and that the brine is evaporated by means of jets of natural gas. At one place the brine is carried five miles by a veritable pipe line (bamboo conduits) to the boilers. The wells are said to have been in operation two thousand years.

PICTURES OF SOUTHWEST AFRICA.

WINDHOEK, the capital of German Southwest Africa, is several hundred miles from the coast, and now can be reached only by a fatiguing journey of several weeks in heavy oxcarts, but next year a harbor is to be built at the mouth of the Swakop River, and then the railroad will be continued from there in the direction of Windhoek; the governor-general of the protectorate, Major Leutwein, has lately visited Germany on business connected with this project. The location of the place is delightful; the plateau on which Windhoek stands is bordered on the south by the Awas Mountains and there are heights on the north and east, and the atmosphere of the dry steppes is so clear that all characteristic features of the landscape stand out sharply like silhouettes. It is exposed not only to storms of the elements, but also of the different tribes; lying as it does between the land of the Hereros and the land of the Hottentots, it was always an "apple of discord" until Jan Jonker, a chief of the Orlamhottentots, laid a firm hand on it. In 1890, however, he was murdered by the tribe of Henric Witboy and the place was left free, but being of strategic importance, it was occupied by the Germans and made the capital of their colony. Their choice of a location was facilitated by the presence of several hot springs that could be utilized for the irrigation of gardens, if, as was to be expected, colonists should settle in the neighborhood. This expectation was soon realized, for at Klein Windhoek—so named for the sake of distinguishing it from Gross Windhoek, from which it is only half an hour distant—huts of industrious German pioneers rose about the half-ruined buildings of the Rheinische Missionsgesellschaft which once had possession of the place. Many have succeeded in wresting a livelihood from this wild and not very fertile land, but others have had to give up the hard struggle, for all are not fitted to bear the hardships that must be endured by colonists in a new country.

But to return to Windhoek: the fort, a solid structure of broken stone and brick, makes quite an imposing impression. It has a court 168 ft. long and 65 ft. 7 in. broad, surrounded by a high wall along the inside of which are arranged the rooms for the garrison. This outer wall is 19 ft. 8 in. high in some places. The fort is strongest at the four corners, which are provided with battlemented towers that could still offer a strong resistance, even if the court were taken by a hostile party, which is extremely unlikely to occur. North of the fort is a long row of buildings placed close together. These include stables, workshops, the prison, guardrooms, police station, officers' dwelling, the messroom and the house of the governor-general's secretary. A little below these lies the house of Major Leutwein, with its stables and pretty garden, and about 300 ft. farther down the mountain side are the government buildings and dwellings of several officials. It will soon be necessary to add to the number of business houses now possessed by Windhoek, as the town has gained considerable commercial importance. The natives, Hill Damaras, with some Hottentots and half breeds, live in square structures with walls of mud covered with clay and roofs made of reeds.

STATION HOUSE AT GROSS BARMEN.

COMPANY OF TROOPS OF THE PROTECTORATE (WITH LIEUT. EGGERS) IN FRONT OF THE FORT AT WINDHOEK.

A strong station house has lately been built at the village of Otjikango or Gross Barmen, which lies on the great highway that runs from the mouth of the Swakop River through Otjimbingwe to Windhoek. As early as 1844 a way station was founded here, near which are a number of hot sulphur springs, which seem to be specially efficacious in the treatment of skin diseases. A special charm is given to the spot by a little group of date palms that were raised from the seed by the first missionaries. These palms seem to thrive well, although their fruit ripens only in most favorable years, and even then its aroma cannot be compared with that of the fruit cultivated in North Africa. Otjikango is of historical importance on account of the numerous battles that have been fought, even recently, in the place itself and in the immediate neighborhood between Hottentots and the Hereros. The inhabitants of Gross Barmen belong to the Ovambandjerus tribe, and they wandered down from the north at the same time as the Hereros, with which race they have become blended.

The Hereros are the most powerful tribe in the protectorate and are looked upon as the conservative element that must be gradually trained and made useful for the common good. They are a fine race of men, with many excellent qualities, but, on the whole, their character is the same as that of the South African Kaffir. New arrivals often consider the Herero a stupid savage, but they soon learn from experience that he is, in his own way, a very shrewd fellow, and what seems like stupidity is only a certain slowness with which he follows the European's line of thought. The Hereros are cattle-raising nomads occupying the central part of the protectorate. Cattle, in fact, constitute their chief possession; they are devoted to them and in caring for them will even work—something they never do willingly. Milk is their chief food. A real Herero is very loath to sell his cattle, and never will part with any but the least valuable animals; he, like the Matabele, prefers to let his dearly beloved cattle die of old age, rather than let them go. Lately the rinderpest has made sad havoc among these cattle, of which some Hereros own many thousands, so that they are very rich, and it is impossible to say where the devastation will end. Christianity found a foothold among these people long ago, but comparatively few have been converted to this faith, because the Hereros are strongly attached to their own peculiar manners and customs. The dress of the Herero woman, who is not uncomely

HENRIC WITBOY AND HIS FAMILY.

CHIEF NICODEMUS AND SEVERAL OFFICERS

in her youth, is most original. On each leg she wears an ornament which consists of several strings of iron beads, twenty or more, according to the wealth of the wearer, and she wears an apron and a sort of bodice or corset composed of strips of leather on which little disks made of ostrich egg shells or balls made from a sweet-smelling root are sewed, and over her shoulders hangs a mantle that is fastened in front. Chains of iron beads are wound around her neck and the upper parts of her arms, while cuffs consisting of coils of strong iron wire cover her wrists. The queerest part of the costume is the headdress worn by married women, which is not unlike a bat's wing in shape. From the back of the top part of the headdress hangs a broad decoration consisting of strings of leather on which are strung little iron tubes or long beads, and these strings are held together by cross strings; this decoration hangs to the knees. The weight of jewelry carried around by a wealthy Herero woman may easily be estimated to weigh fifty pounds. She is not without a certain charm as she walks along with her mantle thrown coquettishly over her bare shoulders, the stiff corset holding her well shaped body straight and preventing any violent movement. She is the picture of natural strength and proud self-consciousness moulded to a native fashion.

Another rather wildly clad race in South Africa are the Bushmen, who still occupy large districts in South Africa, broken up into small bands. They may have been the aborigines, but in Southwest Africa they now resemble the Hottentots so strongly as to be almost indistinguishable from them. They go almost entirely without clothing; an apron that sometimes resembles bathing trunks and sometimes hangs down loose constitutes the only article of wearing apparel for most of them, but the older and more prosperous men and women sometimes wear a mantlelike shoulder covering of leather or fur, the fur being worn next the body. They hunt with the primitive weapons like those formerly used by the Hottentots, the bow with poisoned arrows and the boomerang. The poison for the arrows is taken from the juice of the euphorbia, or from certain insects or snakes. They are a miserable race, and as they have no cattle, they live on what they get by hunting and on wild fruit, and when brought in opposition to the Hereros really have no rights.

The yellow Hottentots living in the south of the land present a strong contrast to the Hereros. As a tribe they are lazy, careless, fond of drink; the former "prophet," Henrie Witboy, is inseparably associated with their history. He wanted to renew the glory of his tribe, who were once the masters of the Hereros, and the latter found him an enemy that was not to be despised. Although he was overpowered many times, he always found new ways of getting on, until he finally came into conflict with the Germans. The authorities warned him many times to give up his warlike attitude and to acknowledge the German protectorate, but he paid no attention to them, even when offered the most favorable conditions, and in 1893 he planned an attack on Windhoek, which he was prevented from making only by the arrival of a reinforcement of German troops. The subsequent events are well known; it was not until 1894 that Witboy's force was compelled to capitulate in Naukluft. Witboy is unquestionably a remarkable, energetic man, exerting the greatest influence over his fellow tribesmen, and at the same time he is cunning to the highest degree. His countenance displays a certain sullen determination. Our engraving of him and his family is a reproduction of a picture taken at Gibeon, the home of his tribe, where he and the remainder of his people were taken as pensioners of the government. The women standing beside him are his daughters, and in front of him sits his son Samuel, with his wife and children. Last year, at the time of the insurrection of the Khaus Hottentots and the Ovambandjerus, Witboy rendered the troops valuable services.

The Khaus Hottentots, who had been placed on a reservation in the south of the protectorate, moved north and seized Gobabis. They were joined by discontented Ovambandjerus, under their chief Kahimema, who had already, in 1894, made an attack on Gibeon during the absence of Witboy. But the real leader of this expedition was Nicodemus, the son of the oldest sister of old Maharero, the great chief of the Hereros. When the old chief died the honor was conferred upon Samuel Maharero, who was friendly to the Germans, and Nicodemus withdrew in anger from Okahandja, to pitch his tents in the land of the Ovambandjerus. By an energetic action of the troops of the protectorate, assisted by Witboy and his tribe, the insurrection was quickly suppressed, after a bloody battle, and the culprits had to endure a severe punishment.—Illustrirte Zeitung.

HERERO MEN, WOMEN, AND CHILDREN IN GROSS BARMEN.

BUSHMEN.

HERERO PRISONERS WITH CHIEF KAHIMEMA, WHO WAS AFTERWARD SHOT.

THE LIPARI ISLANDS.

By E. O. HOVEY.

THE beautiful group of islands known as the Lipari or Æolian Islands lies within easy reach of Messina by way of Milazzo, but rarely does a tourist make his way thither, and most of the foreigners who do visit the islands are geologists who wish to study the volcanic phenomena which are so clearly shown there. Seven islands, Vulcano, Lipari, Salina, Filicuri, Alicuri, Panaria and Stromboli, together with ten islets and numerous crags, form the group. Of these Lipari is the largest and most populous and is best known to the outside world, because it is the source of the pumice stone of commerce. The mountains of this material form a very striking feature in any view of the island from the east or northeast. The scenery of the islands is varied and beautiful, the villages are quaint and picturesque, and the people interesting, but the object of the present communication is to give a brief notice of the geology of the islands and an account of the ascents of Stromboli made on October 27 and 28, 1897, by Prof. H. F. Reid, of Baltimore, and the writer, rather than to dwell upon scenery or political history.

All the islands appear to be purely volcanic in origin, and all except Stromboli rise as more or less distinct cones from a depth of about 1,000 meters below the level of the sea, the cones of Vulcano, Lipari and Salina overlapping one another so as to form a composite series. Stromboli's base may be said to be at the 1,500 meter depth, judging from the contour map of the Italian government as published in Cortese's geological description of the islands. Stromboli has been known as an active volcano throughout all human history of this region, and Vulcano was the site of the forge of Vulcan or Hephæstus in ancient mythology. According to the historian Orosius, the island of Vulcanello, which is connected with Vulcano by a narrow isthmus, was formed by a series of eruptions about B. C. 204, and according to the same authority and Pliny a violent eruption occurred in B. C. 126 which broke up the island of Panaria into the group of islets now located on its site and destroyed part of it. No other eruptions on the islands have been recorded up to 1886, when Gran Cratere on Vulcano burst into a violent eruption of cinders and ashes, destroying the sulphur works which were operated in the bottom of the crater by an enterprising firm of Englishmen, and spreading a mantle of volcanic debris over a large part of the island and far beyond it.

The islands show several typical examples of the formation of successive craters along a line of fracture or weakness in the earth's crust, the destruction of one side of one crater being a preliminary to the formation of the next eruption center. Standing on the summit of Gran Cratere one readily sees that there have been at least four great craters on Vulcano, advancing from south to north, while Vulcanello shows three small ones advancing from east to west.

The visit to Vulcano and Vulcanello is easily made by rowboat from Lipari, and should on no account be omitted from a trip to the Æolian Islands. Landing at the Porto di Levante, one comes first upon the villa

of the proprietor and then upon some of the ruins of the sulphur and chemical works which were destroyed by the eruption of 1888. Everything has a most desolate appearance on account of the mantle of black ashes covering the ground. Some attempt has been made to cultivate the vine, but without much success, and the island is almost destitute of inhabitants, because since the eruption there has not been enough sulphur or sal ammoniac to make it worth while to rebuild the factory. The path up the cone leads one past several large fumaroles on the margin of the old crater ring surrounding the present crater. These fumaroles are surrounded by incrustations showing the characteristic lemon-yellow crystals of sulphur, and the fumes smell strongly of sulphureted hydrogen. The crater is nearly circular in form, rather more than a fourth of a mile in diameter, and two hundred feet or more in depth below the lowest point of the rim. The interior is a simple inverted cone, broken by two terraces on the west and north sides and having a ridge across the bottom which was thrown up by the last paroxysm of the eruption of 1888. The inner slope, though very steep, is not precipitous, except on the south and southwest sides, where the walls of the old crater rim are exposed. Slight fumarole action is observable in the very bottom of the crater and at several points high up on the walls. The great stream of obsidian on the north side of the cone, which is so prominent in Judd's description of Vulcano in his work on "Volcanoes," was covered to a great extent by lapilli and dust during the eruption of 1888.

To visit Stromboli, which lies twenty-two miles from Lipari, one must take a small boat with oars or sails for the journey one or both ways between the two islands, unless he is willing to spend a week on the island, for the steamer service is only weekly. San Vincenzo is the largest of the three hamlets on Stromboli and is the only one where the ordinary traveler can procure any tolerable entertainment. The village lies crowded together on the northeastern point of the island and is somewhat picturesque, like most Italian villages. A peculiar feature is the absence of four-footed beasts of burden. We did not see even a donkey during our stay on the island. Dogs and cats are scarce.

Instead of being a regular cone, as it seems to be from the sea, a glance at the map shows that the island of Stromboli is an irregular trapezium in shape, with its longest diameter from northeast to southwest. Its area is only about five square miles, two-thirds of which is under cultivation, almost entirely with the vine. Above the broad zone of grapevines comes a narrow belt of fig trees, above which is an irregular zone of tall coarse grass much used by the inhabitants in making fences for their vineyards. The upper limit of the grass is about 450 meters above sea level, as determined by Dr. Alfred Bergeat, of Munich, whose exhaustive treatise on Stromboli, published in 1896, should be read with care by those who wish detailed information about the island. A waste of black volcanic sand alternating with streams of lava turned red by weathering occupies the upper half of the altitude of the mountain.

Climbing to the northern summit, 918 meters above sea, one obtains a very clear idea of the volcano and its history. He sees around him extending from the northeast to the south and west the high lava walls of an old crater surrounding the present crater just as Monte Somma surrounds Vesuvius. This lava wall rises on the south to the elevation of 926 meters,* forming the culminating point of the island. Our point of observation is on the wall of an inner crater, and more than 200 meters below us on the north we can see the centers of activity forming the present series of small craters. To make this active crater, the northwestern quarter of the old crater wall was destroyed at a period antedating human history or tradition of the region.

The rim of the ancient crater consists for the most part of andesitic lava, and the steepness of the slope outside the crater on which this lava consolidated is surprising. I measured the inclination on the east side at between 31° and 32°, and the slope seems equally sharp all around. Cliffs giving partial cross sections of the cone show that flows of lava alternated with eruptions of ashes and coarse and fine lapilli in building it up. The lower parts of the old cone show that there have been periods of eruption of other and more basic lavas and the material thrown up in historic time is all basaltic in character.

As far as the writer is aware, all published accounts of Stromboli agree in assigning it constant activity. In ancient times the mountain was known as the "Lighthouse of the Mediterranean," and the beautiful rosy light reflected from the clouds of steam over the crater has often been described as one of the attractive features of a trip by water between Naples and Messina. The activity was such, however, that it could readily and safely be watched from a point near the crater, and the knowledge thus gained has contributed much to the science of vulcanology. Although molten lava could be seen in the bottom of the crater, according to several observers, when it was possible to look over the brink of the crater, all the descriptions speak of the activity as consisting merely of explosions recurring at more or less regular intervals, but the number of eruptive openings reported varied from one to seven. When Bergeat visited the mountain in October, 1894, there were four openings or craters extending in a northeast-southwest line, the largest and oldest crater being at the northeast. He watched the craters for five hours, keeping careful record of the time and character of each explosion from each opening, arriving at the conclusion that no rule could be laid down for either the frequency or the strength of the explosions. These explosions threw fragments of lava high into the air, most of which fell back into the crater from which they originated, but others fell outside to build up the cone or roll down the Sciarra del Fuoco into the sea. Such has been the usual state of things at Stromboli. No one has reported the volcano to be inactive, and only twice in the last hundred and twenty years (in 1881 and 1891) have lava streams been known to accompany an eruption.

In view, therefore, of the record of the volcano a statement of the present condition of affairs will not be without interest and some scientific value. When we visited the mountain there was no eruption in progress. The most southwesterly of the openings described by Bergeat seemed to have disappeared; the second and third were emitting copious clouds of vapor; the "old" crater was giving out but very little steam, though a great deal was coming from the top and outside of its eastern rim. The craters were wholly in the solfataric stage and had evidently been so for some time. Inquiry at Lipari elicited the information from Bartolo Nicotera, the guide to the islands, that there had been no eruption from Stromboli for about a year. An interesting phenomenon was the issuing of hot vapors from the top of the high ridge of tuff, cinders, etc., which rises 230 meters above the southern side of the new craters and is known as the "Cima dello Stromboli." Such vapors are not always rising from this high ridge when the volcano is active. The question as to whether Stromboli will ever resume its activity and again become the Lighthouse of the Mediterranean, as it was for so many centuries, is an interesting one, but one which it is useless to consider. Every other volcano has had its seasons of rest and of activity, and now even Stromboli, after centuries of ceaseless eruption, is having its period of quiet.

* This is the elevation given by the Italian naval chart. The French chart gives 918 meters, the English 3,090 feet (= 926 meters) and Bergeat determined it as 917 meters.

MENTAL EVOLUTION IN MAN.*

By R. M. BUCKE, M.D., Medical Superintendent of the Insane Asylum, London, Ontario, Canada.

ABOUT sixty years ago now, in the time of the Millerite excitement, a man who believed that the world was about to end expressed his fears to Emerson, who replied that it was really a matter of little consequence, "for," said he, "we can do very well without it." There are wise men who teach that each man creates the world he lives in, and as he gives it its substance so also does he give it its quality, insomuch that it is good or bad as he is good or bad. Be this as it may, it is certain that each one of us is of more consequence to himself than is all the outside world, be it shadowy or be it solid; be it created by each inhabitant or be it independent and self-existent. Not only so, but the essential part of each man is what we call his mind, in comparison to which the body is an insignificant factor.

The Study of Psychology.—This being granted, it would seem to follow that psychology ought to be the most interesting of all the sciences, and as a matter of fact it undoubtedly is so, though it has been greatly discredited by the imperfection of the method by which it has until very lately been studied. That imperfection is so great that it would hardly be an exaggeration to assert that nearly all the study and thought expended upon it down to the beginning of our own age has been fruitless and as good as wasted, except inasmuch as it has at last made clear the impassability of the route men have sought to follow, the route, namely, of introspection. For we might as well study the human body alone without reference to that of any other creature, and attempt in that way to decipher its genesis, development and meaning, as to attempt to comprehend a single human mind without including in our examination not only other human minds in all stages of evolution, but equally all other minds to which our own is related—that is to say, all minds other than human belonging to our kinsfolk the animals, minds which stand to-day like mileposts along the almost infinite length of the path which our mind has followed in its upward march across the immensities and eternities from its remote infancy to the present hour; minds which in a thousand faculties represent to us everywhere, in infinite sameness and variety, replicas of our own or of parts of our own, showing us, as the poet says, tokens of ourselves which we "negligently dropped as we passed that way huge times ago."

Comparative Psychology.—As man's bodily life rests upon and grows from that of countless prehuman ancestors; as man includes in his structure the heart of the reptile, the gills of the fish, as well as the forms in outline of innumerable still lower races, so is his so-called human mind rooted in the senses and instincts of all his ancestral species; and not only so, but these senses and instincts still live in him, making up, indeed, far the larger part of his current everyday life; while his higher psychical life is merely the outgrowth and flower of them.

As truly as the plant is an embodiment of inorganic matter vivified by the transmuted forces which in the non-vital world about us we call light and heat, so truly is man's mind the outcome of—the expansion and culmination of—the imperfect sensation of the worm, the rudimentary sight, hearing and taste of the fish and reptile; and the simple consciousness which, springing from these, passed to us after almost infinite ages of slow evolution and amelioration through tens of thousands of generations of placental mammals our immediate progenitors.

In the growth of mind, whether that of the race or of an individual, we recognize two distinct processes: First, the very gradual evolution to, or toward, perfection of faculties that have already come into existence; and, secondly, the springing into existence (as new branches start from a growing tree) of faculties which had previously no existence. For it is clear to the least thoughtful student that no faculty (as no organ) came into mature and perfect life at once. Hearing and sight, we are told, developed by slow degrees from the sense of touch; and in the region of the intellect conceptual life was born from ages of receptual, and that from millenniums of perceptual.

Mental Growth in the Individual and in the Race.—Let us now suppose mind growing for millions of years in the way set forth. It begins, we will say, as mere excitability; to that after a long time is added what may be called discrimination, or choice and rejection of, for instance, different kinds of food. After another long interval of almost infinitely slow advance sensation appears, and with it the capacity of pleasure and of pain; then, later still, memory; by and by recognition of offspring; and successively thereafter arise reason, recognition of individuals and communication of ideas. Concurrently with these intellectual faculties certain moral functions, such as fear, surprise, jealousy, anger, affection, play, sympathy, emulation, pride, resentment, grief, hate, revenge, shame, remorse and a sense of the ludicrous, have also arisen in the nascent mind. We have reached now the mental plane of the higher animals, which is equally that of the human being at about two years of age. Then occurs in the child the mental expansion which separates man from the higher mammals—for something like a year the child mind steadily grows from the status of the latter to the status of the human mind. This year in the individual, during which it walks erect, but possesses a receptual intelligence only, not having yet the power of forming either concepts or true words, represents in the race the age of the alalus homo, the period of perhaps a hundred thousand years, during which our ancestors walked erect, but, not having self consciousness, had no true language. At the average age of three years in the individual self consciousness is born, and the infant, from the point of view of psychology, has become a human being. But we all know that after the attainment of the distinctively human faculty, self consciousness, the child has still much to acquire, both in the way of the expansion of already possessed faculties and in the acquisition of new ones, before it is mentally a mature man. Of the numerous faculties which it still has to acquire I shall mention only here the color sense, the sense of fragrance, the human moral nature and the musical sense. A consideration of these four and of self consciousness will occupy the short time allotted me to-day.

And first a word as to that basic and master human faculty, self consciousness. It occurs, as said, at about the average age of three years, but when it first made its appearance in the race it must have done so at full maturity; perhaps at the age of twenty, both life and childhood being shorter at that time than they are to-day. You will see at once why I say self consciousness must have occurred at first at maturity. Its acquisition at a given epoch supposed a higher mental life than had hitherto existed—such higher life on the part of the race could not have come to the individual before his maturity. To suppose that it would be (if you will think of it) a contradiction in terms. The human mind attains its high water mark at maturity (that is what the word means), and one generation could not reach before maturity what the preceding generation had not reached at all. Well, but self consciousness occurs to-day at three years of age, and we reach full mental maturity (on the average) only at the age of thirty-five. The advance then made by the individual from the age of three to that of thirty-five represents the advance of the race between the date of the appearance of self consciousness and to-day, the mental status of the three-year-old child to-day being the mental status of the adult when self consciousness first appeared. How long has it taken the human mind to grow from mere self consciousness to its present stature? Not less certainly than several hundred thousand years. Whatever the time required, is the time during which man has inhabited the earth.

Of all the mental faculties below self consciousness each one has its own time for appearing in the human infant—as, for instance, memory and simple consciousness appear within a few days after birth, curiosity ten weeks after, use of tools twelve months after, shame, remorse and a sense of the ludicrous—all of them about fifteen months after birth. Now it is to be noted that in every instance the time of the appearance of a faculty in the infant corresponds with the stage at which the same faculty appears (as far as can be at present ascertained) in the ascending animal scale; for instance, memory and simple consciousness occur in animals as primitive as the echinodermata, while the use of tools is not met with below monkeys, and shame, remorse and a sense of the ludicrous are almost, if not entirely, confined (among animals) to the anthropoid ape and the dog.

To turn now to the true subject of this paper, I want to say in the first place that, as in prehuman, so in human psychology, each superadded faculty was acquired in its own time in the history of the race, and that that historic period corresponds with the time in the life of the individual into whom the faculty is born to-day. For instance, self consciousness appears in the individual at the age of about three years—it appeared in the race several hundred thousand years ago. It has been proved by Geiger and others that our color sense has been acquired by the race not more than about thirty thousand years ago. Well, it is acquired by the individual at the age of about five or six. It is thought that the sense of fragrance was acquired by the race later than the color sense; it is also acquired later by the individual. Some considerable study of history has led me to the conclusion that our human moral nature cannot be more than ten thousand years old. For a careful consideration of the records that have come down to us from the early Romans, Hellenes, Hebrews, Egyptians, Assyrians and Babylonians would indicate, I think unmistakably, that, as we go back into the past, this faculty tapers down toward the vanishing point, and that if it continues so to taper as we ascend the ages, all of what we distinctively call our human moral nature would certainly have disappeared by the time we had gone back the number of centuries mentioned—that is, ten thousand years.

Well, to-day the human moral nature in the individual, instead of being born at the age of three years, as is self consciousness, or at five or six, as is the color sense, does not come into existence before the average age of about fifteen years. As to the musical sense, it is almost certainly less than five thousand years old in the race, and, when it occurs at all, is not usually born in the individual before adolescence.

There are three other laws, each well worthy of notice, which govern the acquisition of new faculties by any given race. They are as follows:

1. The longer a race has been in possession of a given faculty, the more universal will that faculty be in the race. This proposition scarcely needs proof—every new faculty must occur, first of all, in one individual, and as other individuals attain to the status of that one they too will acquire it, until after perhaps many thousands of years, the whole race having attained to that status, the faculty shall become universal.

2. The longer a race has been in possession of a given faculty, the more firmly is that faculty fixed in each individual of the race who possesses it. In other words,

* An address delivered at the opening of the section of psychology, at the annual meeting of the British Medical Association at Montreal, September 1, 1897.

the more recent is any given faculty, the more easily is it lost. High authority, such as that of Charles Darwin, could be quoted in support of this proposition; but it scarcely seems to be required; it is almost, if not quite, a self evident proposition.

3. A study of dreaming seems to reveal the fact that in sleep such mind as we have differs from our waking mind, especially by being more primitive; that, in fact, it would be almost strictly true to say that in dreams we pass backward into a prehuman mental life; that the intellectual faculties which we possess in dreams are, especially, recepts as distinguished from our waking concepts; while in the moral realm they are those faculties such as remorse, shame, surprise, along with the older and more basic sense functions, which belonged to us before we reached the human plane; and that the more modern mental faculties, such as color sense, musical sense, self consciousness, the human moral nature, have no existence in this condition, or if any of them do occur, it is only as a rare exception.

Let us now compare, one with the other, a few of the faculties which have been already mentioned in the light of the rules laid down. To do this will give us, more clearly than perhaps anything else could, a definite notion of the growth of mind by the successive addition of new functions. For this purpose we will take simple consciousness, shame, self consciousness, color sense, the human moral nature, and the musical sense.

Simple Consciousness.—Simple consciousness makes its appearance in the human infant at the age of a few days; it is absolutely universal in the human race; it dates back certainly to the earliest mammals, and probably much earlier; it is lost only in deep sleep and coma; it is present in all dreams.

Shame.—Shame is said to be born in the human infant at the age of fifteen months; it is a prehuman faculty, being found in the dog and in apes, and undoubtedly existed in our prehuman ancestry; it is almost universal in the race, being absent only in the lowest idiots; it is very common in dreams.

Self Consciousness.—Self consciousness makes its appearance in the child at the average age of three years; it is not present in any species but the human; it is, in fact, that faculty the possession of which by an individual constitutes him a man. It is not universal in our race, being absent in all true idiots; that is, it is permanently absent in about one in each thousand human beings born into the world. In our ancestry it dates back to the first true man; a race, we are told, unclothed, walking erect, gregarious, without a true language, to a limited extent tool using, destitute of marriage, government, or of any institution, animal, but, in virtue of its highly developed receptual intelligence, king of animals, which developed self consciousness, and by that fact became man. It is impossible to say how long ago it was when this event occurred, but it could not have been less than several hundred thousand years. This faculty is lost much more easily and frequently than is simple consciousness. We lose it in coma and also often in the delirium of fever; in certain forms of insanity, as in mania, it is often lost for weeks, even months at a time; and lastly, it is never present in dreams.

Color Sense.—I have elsewhere written at large on the color sense, and have only space here to give the facts which bear on the present inquiry. That these are facts the argument referred to, I think, demonstrates. This faculty appears in the individual at the average age of about five years. It is absent in one adult human being out of every forty-seven; it appeared in our ancestors, as Geiger has shown from linguistic paleontology, in the Aryan period, probably less than thirty thousand years ago. It is seldom present in dreams, and when it does occur—that is, when any color is seen in a dream—it is generally that color which, for good reasons, was first perceived by man, namely, red.

The following occurrence illustrates (I think in a striking manner) the usual absence of the color sense during the partial consciousness which occurs in sleep. A man whose hair is white dreamed that he was looking in a glass and saw plainly that his hair was not only much thicker than he knew it to be in fact, but instead of being white, as he also knew it to be, it was black. Now, he well remembered in his dream that his hair had never been black. It had, in fact, been a light brown. He wondered (it is worth mentioning here that wonder or surprise is a prehuman faculty, and is common in dreams) in his dream that his hair should be black, remembering distinctly that it had never been so. (I may say here that memory is a prehuman faculty, and is common in dreams.) The important thing to note about the dream under consideration is that, though it was clear to the dreamer's mind that his hair had never been black, yet he did not remember that it had been brown. For some reason (and I think the reason is quite clear) there was a difficulty in calling up before consciousness any color.

Moral Nature.—The human moral nature belongs to a much later stage of evolution than any of the faculties so far considered. It does not make its appearance in the individual before the average age of fifteen years. It is congenitally and permanently absent in at least forty human beings out of every thousand. It would seem clear, as stated already, from a consideration of our historic ancestors, from the fact that this faculty rapidly fades out as we ascend into the past, that it cannot have existed in the race more than ten thousand years at the most. It is far more unstable in the individual than are older faculties, such as self consciousness. It is never present in dreams.

Musical Sense.—Finally, the musical sense (a faculty which is now in the act of being born into the race) does not appear in the individual before the average age of about twenty years. It does not exist in more than half the members of the race. It has existed less (perhaps considerably less) than five thousand years in the race. It is never, or almost never, present in dreams, even in the case of professional musicians.

The Scheme of Mental Evolution.—You see now clearly the scheme upon which I suppose the mind as far as we have got to have been built. I say advisedly "as far as we have got," because, if the mind has grown in the way set forth, it is still growing and is not built, but is in the act of building. No one can ever say positively that his theory (of any fact) is the true one, but I am prepared to say of the above hypothesis that, if it be accepted, it will enable us to understand something of the phenomena of mind as we observe it, whereas, if we should prefer to hold, as many do, that the human mind was created independently of any that preceded it by a fiat and per saltum, then I say deliberately that there is and can be no such thing as a science of psychology, and that every attempt to investigate or explain, to comprehend or divine the rationale of the facts observed as to its origin and growth in the individual must remain forever futile. And, if I could find the right words, I would bring home to each one who hears me the inextinguishable conviction that, in this idea of evolution, lie enfolded the mystery of the past, the explanation of the present, and the sure prescience of the future—what we were, what we are, and what we shall be.

The Atavistic Theory of Idiocy and Insanity.—In conclusion, I desire to refer briefly to two corollaries which flow from this hypothesis. The first is that if it is correct, then all forms of insanity, including all forms of idiocy, are nothing more nor less than cases of atavism. In this view insanity is due to congenital absence or imperfection (leading to breakdown) of some faculty or faculties, such absence or imperfection being due to more or less complete reversion to an ancestral type. In my opinion, this view explains insanity and its numerous forms more completely than these can be explained from any other point of view, and is, therefore, of great value to the thoughtful student of these phenomena. Upon this view the comparatively recent origin and rapid evolution of the human mind, and especially the rapid mental evolution of the so-called Aryan peoples in the last four or five thousand years, is almost solely responsible for the large number of cases of insanity in the modern civilized world, since the stability of any form, function, or faculty in any race is dependent upon the time it has existed in that race, and, therefore, the more recent a faculty is in a race the more frequently will it be found absent, defective or unstable in the individuals of the race.

Future Development of Mind.—The second corollary, which is even more important than the first, is that, upon the view here set forth, the human mind at present is not formed, but forming; is not completed, but in process of construction. By slow and dubious steps taken in darkness our remote ancestors wearily climbed to simple consciousness. After another immense interval they reached self consciousness. But that cannot be the end—the cosmic process cannot stop there—cannot, indeed, stop anywhere. Evolution, as far as we can see, has always gone on, is going on to-day, and will always go on. Our old mental faculties are some of them fading out, others advancing toward greater perfection, and alongside of them new ones are springing up, some of which will, without doubt, be of overshadowing importance in the future.

So-called telepathy and clairvoyance seem to be specimens of such nascent faculties. I place in the same class the phenomena of what is often named spiritualism. The labors of the Society for Psychical Research have made it to me plain that these phenomena, as notably in the case of W. Stainton Moses, really exist. And I think that a study of the above-mentioned case, together with that of Mrs. Piper and that of Mary J. Fancher, of Brooklyn, would compel any unprejudiced person to make the same admission. But to me these are not cases in which outside agents are acting on or through a human being, but are cases in which a given human being has faculties which are not commonly possessed. Whether any given faculty, such as one of those now alluded to, shall grow, become common, and finally universal in the race, or wither and disappear, will depend upon the general laws of natural selection, and upon whether the possession of the nascent faculty is advantageous or not to the individual and to the race.

But of infinitely more importance than telepathy and so-called spiritualism (no matter what explanation we give of these, or what their future is destined to be) is the final fact to be here touched upon. This is that superimposed upon self consciousness, as is that faculty upon simple consciousness, a third and higher form of consciousness is at present making its appearance in our race. This higher form of consciousness when it appears occurs, as it must, at the full maturity of the individual, at about the age of thirty-five, but almost always between the ages of thirty and forty. There have been occasional cases of it for the last two thousand years, and it is becoming more and more common. In fact, in all respects, as far as observed, it obeys the laws to which every nascent faculty is subject. Many more or less perfect examples of this new faculty exist in the world to-day, and it has been my privilege to know personally, and to have had the opportunity of studying, several men and women who have possessed it. In the course of a few more millenniums there should be born from the present human race a higher type of man possessing this higher consciousness. This new race, as it may well be called, would occupy, as toward us, a position such as that occupied by us toward the simple conscious alalus homo. The advent of this higher, better and happier race would amply justify the long agony of its birth through the countless ages of our past. And it is the first article of my belief, some of the grounds of which I have endeavored to lay before you, that a race is in course of evolution.

FURTHER EXPERIMENTS ON THE LIQUEFACTION OF FLUORINE.

By M. Moissan and J. Dewar.

In May, 1897 (Comptes Rendus, cxxiv, 1202), we had the honor of presenting to the Academy our first experiments on the liquefaction of fluorine; we will now describe some fresh experiments we have made on this subject.

Liquefaction of Fluorine.—Our latest experiments on liquefaction were carried out by means of an apparatus similar to that which we have already described, that is to say, a glass bulb fused to a platinum tube, which contained another similar smaller tube; but each of these tubes was fitted with a screw valve in such a manner that at any moment communication, either with the outer air or with the current of fluorine, could be interrupted. This little apparatus was placed in a cylindrical glass receptacle, with double sides, containing liquid air. The whole was connected with a vacuum pump and furnished with a manometer.

In a series of preliminary experiments we determined exactly the boiling points of liquid oxygen at various pressures, as shown by the manometer.

In some former experiments we had shown that fluorine does not become liquid at the temperature of boiling oxygen at the ordinary atmospheric pressure.

We now find that, by repeating the same experiment with freshly prepared liquid air, the fluorine becomes liquid as soon as the air begins to boil at the ordinary pressure.

We have repeated our former experiment, with liquid oxygen as refrigerant, and, on making a vacuum, we find that the liquefaction of fluorine takes place by the evaporation of the oxygen at a diminution of pressure of 32·5 cm. of mercury.

From these two experiments we are enabled to state that the boiling temperature of fluorine is very close to −187°.

Experiments on Solidification.—When the little glass bulb was three quarters full of liquid fluorine, we closed both the valves and then caused the liquid air serving as refrigerant to boil rapidly at a diminution of pressure of 72·5 cm. Under these conditions we obtained a temperature of −210°. The fluorine did not show any sign of solidification, but retained its characteristic mobility. To complete this experiment it becomes necessary to cause the rapid ebullition of the liquid fluorine thus obtained; we hope to achieve this in future experiments. When we had repeated this experiment several times, a slight accident occurred to one of our little instruments containing the fluorine. The screw of one of the valves becoming worn, allowed the air to enter the bulb. This air was immediately liquefied, and in a few moments we had two distinct layers of liquid; the upper, colorless layer consisted of liquid air; the lower one, of a pale yellow color, being fluorine.

In another experiment, taking great precautions to prevent the ingress of any air, the fluorine was introduced in its liquid state into a glass tube, the end of which was then sealed before the blowpipe. The sealed tube, containing the liquid fluorine, was kept for a long time at −210° by the rapid evaporation of a large quantity of liquid air, but it gave no trace of a solid body.

Density of Liquid Fluorine.—To determine the density of liquid fluorine, we brought it into contact with a number of bodies whose density is known exactly. By taking groups of bodies whose densities are very close to each other, it is easy to see which sink and which float in the liquid. This well known though indirect method was the most suitable for these delicate experiments. We first of all satisfied ourselves that the fluorine had no action on the materials used. To effect this we placed a crystal of sulphocyanide of ammonium (density = 1·31) in a glass tube surrounded with boiling liquid air; we then turned in to the bottom of the tube a current of fluorine gas by means of a platinum jet. The fluorine was rapidly liquefied, and the sulphocyanide of ammonium was not attacked. We repeated the experiment with a fragment of ebonite (D = 1·15), of caoutchouc (D = 0·99), of wood (D = 0·96), of amber (D = 1·14), and of oxalate of methyl (D = 1·15). It is of importance, in the experiments we have just mentioned, that the various materials used should be first kept at a temperature of −200° for some little time.

In one of our experiments a piece of caoutchouc, having been insufficiently cooled, took fire on the surface of the liquid and burnt completely away with a brilliant flame, without leaving any residue of carbon.*

The experiment was carried out in the following manner: In a glass tube closed at one end, and of which the lower part had been slightly drawn out, we placed fragments of the five substances we have just mentioned. The tube was then plunged to a third of its length into boiling liquid air. When it was all reduced to a temperature of about −200° we carefully introduced the fluorine gas. This soon became liquefied, and we saw the wood, the caoutchouc and the ebonite floating easily on the surface of the pale yellow liquid. On the other hand, the oxalate of methyl remained at the bottom, while the amber rose and fell in the liquid, appearing to be of the same density. The apparatus was shaken several times, and the quantity of liquid fluorine increased, but the results were always the same.

We, therefore, arrive at the conclusion from these experiments that the density of liquid fluorine is 1·14. Another point which appears to be of interest is the following: The fragment of amber floating in the fluorine was very difficult to distinguish, which would seem to indicate that the index of refraction of liquid fluorine is very close to that of solid bodies.

In another experiment we liquefied fluorine in a glass tube which had been previously graduated; we then sealed the tube, which had been weighed before the experiment, and left it alone in a beaker full of liquid air at the ordinary pressure. An hour and a half afterward, the tube still being in 1 cm. of liquid air, the fluorine had not changed in appearance. But shortly afterward, when the air had all evaporated, a violent detonation occurred; the sealed tube and the double beaker in which it had been placed were smashed and reduced to powder. The sealed tube showed us that liquid fluorine sustains at from −187° to −210° a diminution of volume of $\frac{1}{11}$.

Absorption Spectrum.—We examined with the spectroscope different samples of liquid fluorine through a thickness of about 1 cm., either in sealed tubes or by means of our little condensing apparatus, but we have never been able to detect absorption bands.

Magnetism.—Liquid fluorine placed between the poles of a powerful electromagnet does not show any magnetic phenomena. These experiments are the more decisive, as we made comparative ones with liquid oxygen, as before; they were repeated several times.

Capillarity.—The capillary constant of fluorine is weaker than that of liquid oxygen. A capillary tube

* This piece of caoutchouc ran about the surface of the liquid like sodium on water, giving a very intense light.

plunged successively in fluorine, oxygen, alcohol and water gave the following figures:

Height of liquid fluorine	3·5	mm.
" " oxygen	5·0	"
" alcohol	14·0	"
" water	22·0	"

THE ACTION OF SOME SUBSTANCES ON LIQUID FLUORINE.

Hydrogen.—Liquid fluorine in a glass tube was cooled down by liquid air boiling at a low pressure. A slow current of hydrogen gas was made to impinge on the surface of the yellow liquid by means of a platinum jet. There was immediate combination, with the production of a flame which lighted up the tube. The experiment was repeated by dipping the platinum jet below the surface of the liquid. At this temperature (−210°) complete combination still took place, with a considerable evolution of light and heat.

In another experiment the hydrogen apparatus terminated with a fine glass tube dipping into the liquid fluorine; when the hydrogen was turned on, the combination took place immediately and with violence.

Oil of Turpentine.—Oil of turpentine, frozen and cooled down to −210°, is attacked by liquid fluorine. To perform this experiment we placed a little oil of turpentine at the bottom of a glass tube surrounded with boiling liquid air. As soon as a small quantity of fluorine was liquefied on the surface of the carbide the combination took place with explosive force, a brilliant flash of light and deposition of carbon. After each explosion the current of fluorine gas was kept up slowly, a fresh quantity of liquid fluorine was formed and the detonations succeeded each other at intervals of from six to seven minutes. Finally, after a longer interval of about one minutes, the quantity of fluorine formed was sufficient to cause at the moment of the reaction the complete destruction of the apparatus.*

Oxygen.—The action of liquid oxygen has been studied with much more care, since we observed from our earliest experiments that by passing a current of fluorine through liquid oxygen we obtained a detonating body.

If we bring a current of fluorine on to the surface of liquid oxygen in a glass tube, the fluorine dissolves in all proportions, imparting a yellowish color, and giving the liquid a graded tint from the upper to the lower part; the bottom of the tube is hardly colored. If, on the contrary, we introduce the fluorine gas at the bottom of the liquid oxygen, the yellow color is produced at the bottom and diffuses slowly to the upper layers.

This phenomenon indicates that the densities of liquid fluorine and oxygen are very near each other. When we have obtained a mixture of liquid oxygen and fluorine, if we allow the temperature to rise slowly, the oxygen evaporates first. The liquid becomes more and more concentrated as to fluorine, and finally the latter begins to boil in its turn. In fact, at the commencement of this boiling the gas coming off will light a match which has only a red hot point, and will not make lampblack or silicon red hot; but, on the other hand, the gas coming off at the end of the experiment will instantly cause these two latter bodies to burst into flame. When the glass bulb is completely empty and its temperature is rising, we suddenly notice a distinct disengagement of heat, and the interior of the glass loses its polish. This rise of temperature is due to the fluorine gas attacking the glass. In this experiment, when using perfectly dry oxygen, no precipitate is produced. If, on the contrary, we use oxygen which has been some hours in contact with the air, the detonating substance we mentioned in our previous communication is produced with great readiness.

In one of our experiments, in which we tried to obtain a suitable quantity of this body, we had an explosion strong enough to smash the glass in which the experiment was being performed.

To sum up, this body, which is produced by the action of fluorine on moist oxygen, seems to be hydrate of fluorine, decomposing, with detonation, by a simple rise of temperature.

Water.—We froze and cooled down to −210° a small quantity of water at the bottom of a glass tube. Liquid fluorine formed on the surface of the ice as a mobile liquid without action, and it evaporated on the temperature rising. As soon as the apparatus became warmer the remaining gaseous fluorine attacked the ice with great energy, and we noticed a strong smell of ozone.

Mercury.—We solidified a globule of mercury at the bottom of a tube. The surface remaining very brilliant, the liquid fluorine surrounded it without causing it to lose its appearance or polish. On allowing the temperature to rise to −187°, the fluorine began to boil, the liquid disappeared completely, but the attack of the mercury by the fluorine gas did not take place until the apparatus had almost reached the temperature of the laboratory.

CONCLUSIONS.

Fluorine gas is easily liquefied at the temperature of boiling atmospheric air. The boiling point of liquid fluorine is −187°. It is soluble in all proportions in liquid oxygen and in liquid air. It does not solidify at −210°. Its density is 1·14, its capillarity is less than that of liquid oxygen; it has no absorption spectrum and it is not magnetic.

Finally, at −210° it has no action on dry oxygen, water or mercury, but it reacts, with incandescence, on hydrogen and oil of turpentine.—Comptes Rendus, cxxv, No. 15, p. 505, 1897.

In his monthly report to the Chief of Engineers Col. T. W. Bingham, Commissioner of Public Buildings and Grounds, says that 10,801 persons went to the top of the Washington Monument during October, and 3,317 of them walked. Since October 9, 1888, when the monument was opened to the public, 1,453,555 persons have gone to the top.

Olive growing on the Italian Riviera is giving way to the cultivation of flowers, chiefly roses and pinks, for the London and Paris markets.

* In several of our experiments we accidentally let a little liquid fluorine fall on the floor; the wood instantly took fire.

ROLLER BOATS.

The Bazin roller boat is slowly proceeding with experiments that up to the present have not completely responded to the hopes of its inventors. It is very certain that in the preparatory studies certain factors were neglected that intervened in large proportions to diminish the speed that it was expected to obtain. Thus, in an experiment made upon the Seine, in an unobstructed course, the speed did not exceed eight or nine knots with the propelling and rotary engines developing their full power. According to calculations, from eighteen to twenty knots ought to have been obtained. The two resistant forces that have the most action are adhesion and the friction of the water against the rollers.

Fig. 1 represents one of the rollers supposed to be moving at a velocity of from ten to twelve revolutions at the fixed point. The water is carried along to the upper part, not only upon the external circumference, but also upon a large part of the spherical cap. There is thus produced a great resistance which it will never be possible to get rid of, even as has been proposed, by covering the wheels with a coat of varnish or with a fatty substance.

The second cause of resistance is due to the friction of the water against the four rollers, the submerged surface of which is quite wide. It has often been said that in the Bazin roller boat rolling friction is substituted for sliding. This is true only in part, since, in consequence of the speed of the boat and of the revolution of the rollers, there is developed upon the submerged portion of the latter a force of sliding friction that there is reason for taking into account in the appreciation of the results.

There is another drawback that this type of vessel will always present, and in regard to this all mariners are unanimous, and that is the difficulty, not to say impossibility, that will be found of remaining at sea in foul weather.

One must never have seen the water of the ocean during a squall of wind, and consequently be ignorant of the power and violence of the waves, to believe that such a vessel is capable of resisting them. It would, as sailors say, be swallowed by the sea, even were it capable of supporting the stresses that huge waves, breaking under the foot bridges, would exert upon the latter and cause the whole thing to capsize.

Fig. 2, which represents the stern of the roller boat, plainly shows to what dangers the four faces of such a vessel are exposed.

Fig. 1.—STERN LARBOARD ROLLER.

It may be added that, were the Bazin roller boat to make the high speeds predicted by its inventors, it might be utilized upon lakes and large rivers for the carriage of passengers, since there is not enough space upon it to permit of doing a large freight business.

The idea of constructing a boat to roll upon the sea is not new. The Call, a San Francisco newspaper, in its issue of November 20, 1895, devoted an article entitled "To Roll upon the Water" to the description of a vessel that was to rival the fastest trains in speed (Fig. 5). Mr. Chapman describes his invention as follows:

Fig. 2.—VIEW OF THE STERN OF THE BAZIN ROLLER BOAT.

Between two huge cylinders are suspended the hull, the deck and the cabins for freight and passengers. Along each side are the foot bridges that connect the axes of the two cylinders. Upon these axes, which are fixed, revolve, in ball bearings, the bases of the two cylinders and, consequently, the cylinders themselves.

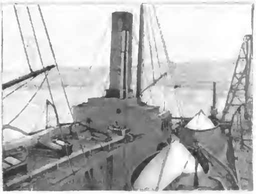


Fig. 3.—STERN LARBOARD AS SEEN FROM THE FOOTBRIDGE.

In order to obtain the motive power necessary for the motion, there is placed upon the internal surface of the cylinders an iron track upon which runs a locomotive moved by electricity. As soon as this locomotive begins to run, the large cylinders will begin to revolve. The inventor has found by experiment that a very large wheel revolves with greater ease when the motive power is applied as described above. The height of the engine has considerable influence in proportion to its weight, and a very high speed ought thus to be obtained. What will the latter be? Mr.

Chapman cannot say, but he sees no reason why it should be less than that of the modern railways.

The trip from the United States to England might be made in three days or even in forty-eight hours. There would thus be greater chances of passengers making such a trip without seasickness. Here and there, upon the generatrices of the cylinders, there are projections that will cause the latter to move forward instead of simply revolving. Besides, in the center of the height of each cylinder, and at right angles with the generatrices, there is arranged a projection that is higher than the preceding and that will subserve the same purpose as the keels of the present ships. Rudders may be placed at the stern on each side and be connected with the fixed axes.

With cylinders of a hundred feet or more and a space of from four to five hundred feet between the two, rolling and, consequently, seasickness will be almost entirely prevented.

It is well to remark that the locomotive will always keep the same position with respect to the axes, that is to say, at the bottom of the cylinder, whatever be the speed. In this way, it is possible to enter the interior of the hollow axes through the lateral foot bridges, and from there to ascend by a ladder to the engine.

The most interesting part of the invention consists in the reduction of the net cost. It is possible, in fact, to save nine-tenths and even nineteen-twentieths over the price of an ordinary vessel. Instead of huge boilers and engines that necessitate an army of stokers, there will be need of but two locomotives. In cases in which a great speed would not be obtained, the diminution in the net cost would again render the invention useful, particularly if it were a question of operating upon rivers or canals, where freight charges should be low. It is the great problem of the future to be able to increase the speed of ships upon canals without injuring the banks. Screws and paddle wheels are not practical, on account of the violent motion of the water that they produce. With this new vessel, the cylinders will simply roll over the water without the least agitation of the latter, even at the highest speed of the largest ocean steamers.

As may be seen from this brief description, Chapman's roller boat must have the same qualities as Bazin's. It is probable that the results anticipated by the inventor have not been obtained, for, since 1895, this new boat, which was to revolutionize the art of naval construction, has not been heard of. We hope that the Bazin roller boat will have more success than its predecessor.—*La Nature.*

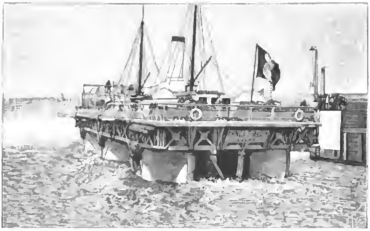

FIG. 4.—GENERAL VIEW OF THE BAZIN ROLLER BOAT.

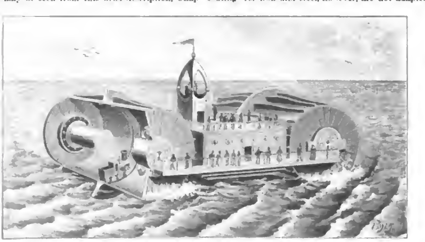

FIG. 5.—THE CHAPMAN ROLLER BOAT.

On October 19 the Illinois Steel Company turned out 1,248 tons of rails and billets on the day shift of 12 hours and 1,160 on the night shift, or 2,408 tons in 24 hours. They expected to turn out 47,000 tons in [illegible]orld's record.

NOTES ON THE YACHT DEFENDER AND THE USE OF ALUMINUM IN MARINE CONSTRUCTION.

By RICHMOND PEARSON HOBSON, Assistant Naval Constructor, U.S.N.

IN a paper contributed to the United States Naval Institute, Annapolis, Md., Mr. Hobson presents an exhaustive scientific report on the construction of the Defender and other aluminum craft, the corrosion of aluminum from salt water, and the present and future uses of aluminum in marine construction. The complete text of the paper is published in a recent number of the Institute. In reviewing the subject of corrosion Mr. Hobson writes as follows:

The experience in actual service and the experiments made are inadequate to a definite and final conclusion as to the corrosion of aluminum in salt air and salt water.

The consensus, however, would lead to the following general conclusions:

1. When isolated, pure aluminum is not attacked.

2. When isolated, the usual alloys of aluminum and commercial aluminum are attacked in a measure more or less proportional to the amount or per cent. of the alloy or impurities. Among the alloys, copper and zinc seem the most corrodible.

3. When in contact or communication with other metals below it in electrochemical scale, galvanic action sets in and aluminum and its alloys are rapidly corroded. The action takes place when the contact is between different alloys of aluminum and even between different pieces of the same alloy, when not homogeneous; and there is indication that the corrosion of isolated alloys is probably due, in large measure, to the galvanic action between the particles of the two metals in the body of the alloy. Copper is again the metal whose contact causes most accentuated action, and the copper alloy is the alloy in which galvanic action is most marked.

4. The conditions of corrosion can be ameliorated by the application of coatings and covering. The usual coatings for iron and steel, however, are not adapted to aluminum, particularly red lead. In case of special coatings, as yet prepared, special care and frequency of application are required. It would seem that the special characteristic to be sought is impermeability.

While drawing the above conclusions on corrosion, the imperfect behavior of steel and iron should be borne in mind. With full appreciation of this imperfection, however, the comparison of the two metals gives the following general results:

1. At the present stage, structural aluminum is materially more subject to corrosion than steel. The marked corrosion, however, must be attributed to galvanic action due to the high electropositive character of aluminum, the pure metal itself, practically incorrodible, being far ahead of steel, and to this galvanic action must be attributed the corrosion of alloys and the usual commercial aluminum where even there is no external contact with other metals, the action taking place in the body of the metal from the intimate contact of the molecules of aluminum with the molecules of the alloying metals or impurities.

2. This feature of inferiority must therefore be regarded as subject to future amelioration from increase of knowledge and selection in the preparation of the alloys and from improvement in conditions of insulation and protection. Substantial amelioration has already been found in the use of nickel for the alloy, without entailing loss of strength, while further amelioration seems promised in the use of tungsten for the alloy.

Special measures toward insulation seem not to have been taken or tested in any case.

3. The coatings used for painting steel are not effective in protecting aluminum, and the special coatings as yet prepared are but partially effective, and then only on condition of special care and frequent renewal.

4. This feature of inferiority must likewise be regarded as subject to future amelioration with further experiment and increase of knowledge. It could scarcely be expected to find a suitable coating without research, particularly when the usual coatings for steel are composed so largely of oxides of metals whose contact with aluminum sets up galvanic action.

5. The degree of importance of the inferiority of aluminum to steel in the question of corrosion varies with the conditions of exposure, and is disqualifying when the exposure to salt water and spray is constant and where frequent visitation is difficult or impracticable.

The cost of maintenance and care and the length of life identify themselves, as seen above, with the question of corrosion. Without being able, evidently, to assign definite values, the cost of maintenance and care at the present moment must be taken as appreciably greater for aluminum than for steel. The cost of additional care is not of great consequence for parts easily accessible, provided the exposure is not great and the coatings applied or the other process of care are at all effective. For parts constantly exposed, multiply the frequency of visitation; the additional cost is considerable, particularly where the parts are difficult of access. In such cases of exposure and difficulty of visitation, the inferior conditions of preservation reduce the length of life, which, under good conditions even, must be considered as shorter than the life of steel. This factor of cost takes on large proportions and, at the present moment, must be considered prohibitory for waterwashed surfaces and parts in contact with bilge water, while still of large consequence for all outside parts, topsides, upper works and upper deck fittings.

The results of the comparisons for strength and weight and for cost lead to the conclusion that at present aluminum is adapted for use in hull work for bulkheads, casings and trunks, small trunks and ducts, hammock berthing and metal ceiling, and for use in hull fittings for parts of ventilation system, for metal doors, hatches, torpedo ports and coaling ports, metal ladders and gratings, masts and spars, this adoption in the case of a 9,000 ton vessel realizing a saving in weight of about 380 tons, at an increase of about $250,000.

The same results lead to the conclusion that as soon as an efficient coating is found, aluminum will be further adapted for the bottom plating of sheathed vessels, for the bottom and topside plating of small vessels, part of the topside plating of large vessels, for bottom and topside framing of small vessels, for topside framing of large vessels, for the bottom framing of large vessels, except outer angles in double bottom, for inner bottom plating, and deck plating, and for dead light, airport and deck light frames and casings, realizing by this adoption in a 9,000 ton vessel a saving in weight of about 380 tons, at an increase of cost of about $260,000.

It is to be remarked that in the above applications it is assumed that galvanic action does not set in from the contact of aluminum and steel, an assumption apparently justified by experience thus far; but, in course of time, it is largely probable that appreciable action would set in, if some insulating provision were not made in the joints between the two metals. It is not believed, however, that such insulation provision would be impracticable.

It may be recalled, also, as stated in the outset, that performances and homogeneity of aluminum as taken are somewhat ahead of the present stage of manufacture, and that the applications have been extended to dimensions and scantlings not yet commercially turned out.

Moreover, it should not be overlooked that the element of cost in the maintenance and care of aluminum construction and the length of life are not well determined and are difficult to valuate on account of the limited experience.

The results arrived at are thus to be taken in connection with the limitations necessarily imposed by the fact of the field being essentially new.

In summation and in conclusion, aluminum has incontestable virtues as a structural material. Its great elastic elongation and resistance within the elastic limit places it far ahead of steel for resisting usual, well determined and repeated dynamic forces, while its great comparative lightness marks it for marine construction. On the other hand, it has serious defects. An excessively low elongation beyond the elastic limit unfits it entirely for use where liable to be subjected to violence and unknown dynamic forces; temperatures beyond atmospheric undermine its physical properties; while notwithstanding an innate superior resistance when pure to the attack of corroding agents, the high position on the electrochemical scale, causing excessive tendency to galvanic action, places a severe obstacle in the way of adoption where exposed to salt water and spray, particularly in the case of alloys, in which form alone the metal exhibits its best properties. This last serious defect, however, must be considered as subject to constant amelioration with increase of knowledge and experiment in precautions and higher perfection in manufacture.

Thus, while this new metal has an important field in marine construction, an important field now ready for occupation and additional fields awaiting only the improvement in conditions for resisting galvanic action, these fields are essentially limited, and the larger domains are shut out by impassable barriers.

The early optimist who inferred all virtues from a

single virtue, and the latter reactionist who pronounced general unfitness from a few partial trials, were both wide of the mark. The metal is not Utopian, but it has nevertheless beyond question an important mission for the serious marine architect, who is only waiting further improvement in manufacture and reduction in cost and further amelioration in conditions of corrosion.

For the naval architect of our own country, for our country itself, the question has a special significance.

The maintenance of a strong commissioned naval force must be our country's policy for taking its destined part of international greatness in regulating the common affairs of the planet, but our position and the spirit of the nation marks our naval policy specially for a great force kept economically in reserve commissioned only periodically for drill purposes.

In a state of reserve the conditions of corrosion are greatly ameliorated. The vessels seek and lie in fresh water; the torpedo boats and small boats, which do not seek fresh water, are hauled up under sheds. Under these conditions the great obstacle of corrosion is largely removed from aluminum's path. Indeed, aluminum appears to be superior to steel in resistance to the corroding effects of atmospheric exposure and of fresh water.

The question becomes more significant where account is taken of the great natural facilities and possibilities of our coast line for fresh water basins of large expanse for taking vessels of all sizes. It takes on a still more significant aspect when it is recognized that nature in the inland routes along the coast has marked small craft as our great second line of defense, while in the inland waters of great rivers and great lakes in communication with the sea she has provided immeasurable possibilities for the construction and maintenance of these craft.

Torpedo boats, which are thus marked for a great natural economical branch of national defense, form now the least developed arm of our navy.

There therefore lies ahead, inevitably, a vast programme of torpedo boat construction, for which every advantage of materials of construction should be earnestly sought. Fortunately for the nation, this branch of defense admits of rapid growth and may be expected to have large expansion in the near future. Indeed, the time is not very far distant when, with treaty restrictions abrogated, we shall see on the great lakes vast flotillas of torpedo boats, lying for most of the year in economical reserve free from corrosion. Periodically they will be commissioned for drill purposes and from time to time will sally forth to the seaboard for mobilization and exercise in the operations of coast defense.

We would realize thus, at a minimum cost and a minimum turning away of the nation's energies from the channels of production, a great power, tranquil in time of peace and good will, irresistible for defense in time of war.—Aluminum World.

THE CONDITION OF THE LABORING CLASSES IN MEXICO.

UNDER the joint auspices of the Franklin Institute and the Young Men's Christian Association, Mr. Theodore C. Knauff recently delivered, at Association Hall, Philadelphia, an illustrated lecture under the above title, from which the following excerpts are taken.

A year ago a newspaper paragraph said, "Why is it that the Mexican peon with his sixty cents a day is making more than the American farmer with all his knowledge and invested capital?" The untruthfulness of this parallel is proved by a trip to Mexico to study the peon's life, followed by a trip through Iowa, Wisconsin, etc., to see how the American farmer lives, personally, what percentage are mortgaged, what have paid off their mortgages, what have a bank account and what percentage have money loaned out at interest. In the last presidential campaign Mexico was held up as a great country for the manufacturer and far beyond our own in prosperity; that thither the workingman must go to find the only prosperity then obtainable.

Mexico is not such an insignificant country compared with ours, either in size or wealth; and it was a land of comparatively advanced civilization long before Columbus discovered America, having a representative government and a fairly complete system of laws. With the European advent into and conquest of Mexico she received and absorbed all that was then known of eastern civilization, at a time when all but a very small proportion of this country was inhabited by savages. After a year's exhaustive study of the subject, Mexico now has a certain amount of prosperity; but she went to sleep for several centuries through religious intolerance and did nothing; suffering also from instability and mismanagement in government and from internecine wars. A long series of years overcame all this; she lived again, though behind in the race; and in her effort to catch up developed great opportunities for capital. To that extent it was a newer country than our own, with more chances. About 1890, suffering through a long disaster, from an unmanageable foreign debt, she tried to lift it by virtual repudiation; the man owning a dollar in Mexico knew not how long it would be his; or, having a dollar loaned, how soon he could get it back. Mexico is a silver country, not only by this monetary basis, but as a producer of silver, all its interests, all its industries, are wrapped up in this product, constituting 60 per cent. of her exports to-day.

At a most critical time President Diaz was confronted with an enormous decline in the value of this national commodity, which must be measured by the foreign product; he faced a great foreign debt contracted in gold, principal and interest—having naught but silver wherewith to pay. $100,000,000 was the gold debt, besides additional debt contracted in silver. That gold debt, comparing the number of their people with ours, is as large as all our national debt; and much larger, comparing the quality of their people with ours. Mexico wanted to borrow money. Should she pay this debt in depreciated silver and thus virtually ruin her reputation? It meant stagnation and ruin. If she simply went to work and paid her debt (just double in face value what she had contracted to pay), that meant stability. Diaz undertook the great task of getting just double this amount of money, which in his country took just twice as long to get—very expensive process, but it paid in the end. To-day, when Mexico wants more money (which she always does), she can get it. The foreigner will loan it, because he knows it will be paid back. Mexico has many multimillionaires who live there and will loan their money to the country; there must be activity and what we call prosperity under such circumstances. Here is the admitted prosperity of Mexico; who benefits by it? Has she been a haven for the unemployed? No. Labor is governed, among other things, by the law of supply and demand. So is capital. Here is a country needing capital, and it is in short supply. On the other hand, here was a country having an unlimited amount of labor, very low priced and largely unemployed, ignorant, and so indolent it was incapable through improved conditions to help itself along; consequently, there was no rise in the price of labor. The wealthy man came along and enriched himself under the advantage of low-priced labor, was invited to go there and virtually wring his profits out of the workingman. It was not a place for the workingman, but for wealthy men to make money out of the workingman. Their low-priced labor is the greatest inducement they put forward for foreign capital. The American silver mine operator is attracted there because the Mexican smelter or miner works for half what the American does and is contented. He lives, apparently happy, on food in quantity not enough for an American child and in quality not the proper thing for an American hog. This cheap labor has been the very source of this cheap money; and this workingman has borne the brunt of what has taken all the efforts of the country to lift in the way of debt. There is no country in the world that is better for monopolies and trusts than Mexico. What has she paid for her prosperity? She is borrowing money all the time to meet the great deficiencies; no means of raising revenue are neglected, and they are all borne by the workingman. If the workingman wants a little delicacy, or a little amusement, he must pay for it in the way of taxes. It is only lately that a middle class has begun to spring up. The wealthy American individual or corporation, going there, puts out money under great concessions—getting advantages virtually wiping out taxation. So, too, the great Mexican land owners form so strong a combination as to virtually rule the country and practically exempt themselves from taxation. The rest comes out of the poor man or the middle class man.

This new Mexico, which is the result of foreign and domestic capital being spent, is apt to be neglected. Because there is so much of the workingman that is picturesque, we neglect the rich man. We went to see how this workingman lives; how he is housed and clothed.

A map of Mexico, projected upon a United States map of the same scale, extends from Maine to Texas. Mexico is sixteen times the size of New York State; Sonora equals Indiana and Ohio combined; Chihuahua, Pennsylvania and New York combined. Mexico's mountain system is a continuation of the Andes widening out into two ranges, leaving in the middle a high, flat tableland, 4,000 to 8,000 feet high, with a volcanic range through it reaching 18,000 feet. The citizens of the capital, Mexico, at 8,000 feet, are 2,000 feet higher than Mount Washington all the time. We feel that altitude, the dryness and rarefaction of the air; and we do a great many things, from atmospheric and surrounding conditions, that we would not do in our own country. Altitudes affect climates more than latitudes. Entering Mexico from El Paso, Texas, we cross over from Torreon on the International Railway to Monterey and Tampico (the latter a seaport); then climb the mountains again to San Luis Potosi on the tableland. At Guadalajara is the great gate made shortly after Cortez entered the country; thence down into the city of Mexico and along the trail of Cortez through some of the grandest scenery in the world, to the seaport Vera Cruz.

Egypt is the only country equaling Mexico in fullness of interest for travelers; and no other frontier in the world presents changes so sudden and so marked as that at El Paso. Everything on the American side looks prosperity; the express wagons, the Pullman coaches, the ordinary American citizen, freight houses, oil shops and factories. Crossing by almost a dry ditch (the water being used for irrigation purposes) to the opposite Mexican town, we pass, in a few seconds, to conditions changed as by a magician's wand. For coats, we have blankets; for hats, sombreros; for prosperity, poverty, by appearance; for a self-respecting population, loafers and beggars; the greatest possible interest in our arrival, the town turning out as to the one event in their lives, conveying the impression that no occupation whatever could be found in the place.

Mexico's population is 12,570,000, two-thirds of whom never slept in a bed, wore stockings, rode or had an ancestor that knew how to ride; and they live to-day at a less expense per man than it costs us to keep the meanest farm horse. Fifteen years ago travelers could not go around unattended. One of the first persons we meet on entering any of the towns in Mexico is the brigand. The Mexican government, when necessity demanded, took two ways of ridding itself of them: one, by sending out troops, putting him against a wall and shooting him; but the leaders were turned into soldiers and put there to catch brigands—a very successful proceeding. The flower of the Mexican army to-day is the Rurale, or rural fellows, the most expert soldiers and riders; at every railroad station are two of them detailed to guard the train and preserve order. The rails of the track bear the best known English stamp or come from Krupp's, in Germany. Iron is very scarce and dear in Mexico, simply for want of capital to get it out. Near the station of Durango is a mountain of nearly solid iron, assaying 90 per cent. metallic iron—enough to supply the world 300 years; but within a very few years iron was sold there for 35 cents per pound.

By whatever route you enter Mexico you must necessarily pass over a desert. In the northern part it only rains during the summer months, and then not even every year. So on all trains the locomotive carries an extra tank car. The question of transportation and the scarcity of water are two pressing problems in that country to-day. Wood costs $12 to $18 wholesale; and what there is has to be cut for railway ties, except when they use iron ties. Coal is also scarce, although there is plenty along the railroads, but it has not yet been mined. The Vera Cruz Railroad imports its coal from England at $20 per ton; while the roads in the north get theirs from Colorado.

On the Mexican tableland the houses are almost universally built of adobe, simply a large block of mud pressed into shape in a mould, then hardened and baked in the sun and laid in flat layers, one on top of the other, in walls 20 inches thick. It makes quite a substantial building, requiring a long time, even in the rainy season, for the water to soak through the walls. A church and a plaza are required before a settlement can be a city. The Mexican farm laborers and their conditions are far inferior to those of the late slaves of our Southern States. The huts have but one opening; no window; no drainage; dirt floors; and the occupants, regardless of sex, wishing to go to bed, simply unroll their mats and, without removing clothing, go to sleep. There are no seats, no utensils other than the pots for cooking and mill for grinding corn. The farm laborer has a certain wage and is given time and place to build himself this house; if he does not build it, he has no house. All these houses are built by the people who live in them. They vary, in some places being mud roofed, in others roofed by palms, or banana leaves or some fiber that will shed moisture when necessary. In the city, they look to the eye as if not built of this mud material, but are exactly similar, except the exterior is plaster coated, resembling our pebbledash. Outside is no particular mark of beauty; but within, the pateo, or hollow square, is bespangled with flowers and very homelike in its surroundings.

The city streets present all one-story houses; dirt floored or tile floored. If any one is so extravagant as to own a carpet, that is put down directly in the doorway. Ventilation is unprovided for, and were it not for the exceedingly dry air, due to the elevation and absence of moisture, the mortality would be frightful. City houses of a better class are made of stone. In constructing an arched extrance they build a form the size and shape of the arch and then build upon it, and when the keystone is in place they take the form away. Many of the houses are unfinished, not because they have not had time, but they do not want to do the work. Also, in some towns, all finished houses are subject to tax; therefore, a great many houses are unfinished. This is the condition, also, of a certain railroad in Yucatan which is being built under government subvention, which subvention they were to receive only until the road was finished. That road, for some twenty years, has been within one mile of being finished.

To see a man working a modern sewing machine in the street is not unusual. All branches of trade are carried on outside in that way. Should you want your shoes repaired, you will find a cobbler on the sidewalk or at the curb, wherever it is convenient for him to be. A policeman on duty in a certain municipality I noticed attending to a piece of knitting; in another, one of the regular government sentries, near a government station, on sentry duty, with bayoneted gun leaning against a wall, while he engaged in what the ladies call their "drawn work"—embroidery.

The wealthy families in the three and four story houses live upon the upper floors and don't care who occupies the others. A person of means has invited you to dinner; you find, after considerable trouble, the stairway and eventually a very small bell pull with his official title underneath. You ring and are at once ushered into the greatest magnificence—all kinds of comforts; and there you find genuine Mexican hospitality, the usual speech (in Spanish) being "The house is yours."

There are shops, but business is conducted largely by peddlers and sidewalk merchants. You find not the shop owner's name over the doorway, but instead an official title, which is the name of the shop. Mexican bread is raised with pulque (the equivalent of yeast) and is always sour, and the bake shop where we tried to get something approaching Mexican bread that we could eat bore the name over the door "La Favorita." A druggist's name, being translated, was "Gate of Heaven." Another was a saloon and bore the name "Port of New York." In still another town (probably a prohibition town) the saloon was called "The Triumphs of the Devil."

In the neighborhood of Zacatecas we found the people gathered about noon around the central fountain. This is a town in which the water is very scarce indeed, the central fountain being the town's sole supply, and the fountain deficient at that. The people have to come very early to get a supply for the day. The supply that comes in the night runs out very quickly, and they have to take the water up in little scoops until the vessel is full. I have been asked, If this be true, what do they drink? There is plenty of water to drink, but not enough for ordinary purposes from our standpoint.

The women wear a kind of cotton shawl over the head or shoulders called a reboza, and the men a woolen garment called a sarappe. Transportation is forced upon our attention, because at every turn on the railroads we see the primitive oxen carts of Cortez' day beside our modern train—an ox cart whose wheel is of three solid pieces of wood. The people who run those wagons—the teamsters—get for their pay fifty cents Mexican per day. The teams themselves are owned by the wealthy proprietors. The oxen are hitched, not by a yoke, but by being tied to the horns—the strongest part of the animal.

The railway traverses a region of great border farms; on both sides, at one place, for eighty miles, is all one large landed estate, belonging to one individual. In another place one estate has 1,500,000 acres; in another, 250,000 acres. Out of a total population of 12,570,000, 6,000 people own all the land, with influence enough to avoid, practically, all taxation, which falls on the poor; and so there is no middle class. At present there is little danger of an uprising of the people, because they are generally content; and if they had a leader there to create an uprising, no one would follow him. The giant cactus grows there—a variety of what we call the prickly pear—bearing a fruit; the leaves are fed to cattle after burning off the thorns, and it is the national plant of Mexico, seen on the Mexican dollar. A species of this plant was used to feed the cochineal insect until the use of aniline colors threw cochineal out of the market; in fact, all the vegetation of the country seems to wear a thorn.

The sarappe, the ordinary garment of the Mexican, is quite thick and of wool; and you might think the people were suffering from the cold. One garment is his coat—sometimes his hat; it is his bed, and numerous other things. It is made usually with a slit or hole in the middle; and when a man is liable to do anything else and wants the use of his arms, he pokes his head through the hole, and when he does not want to do that way, the hole is simply sewed up and he wraps the garment around him.

The feet are usually bare or clothed in a domestic sandal. We sometimes see a white cotton garment, more suitable for the hot countries; but strange to say, we find more of that kind in the tableland, where it is cold, and the sarappe in the lower land, where it is hotter. They simply reverse things. When Cortez entered the country he found the natives all clothed in cotton; it is the native plant; and the armor of the soldiers of the Aztecs who fought Cortez was made of quilted cotton, made to turn back the arrows used between those Indian tribes, but affording no protection at all against the firearms of the Spaniards. In some cases, when our pegged shoes have been sold in Mexico, it has been found that the air is so dry that the pegs drop out and the soles come off, when the soles are used as sandals.

There are to-day in Mexico pure breed Indians—Aztecs of exactly the kind that fought against Cortez; of pure blood, speaking the Aztec language; some of them may be found in the streets of Mexico, and they are of a peculiar bright red—very clannish; they could not have preserved their integrity if they had not been. There are twenty-five original languages of the Indians spoken in the country to-day. All grades of peons are more of the Indian type; but they range all the way from that common class of mixed blood up to nearly pure, true Spanish blood.

The better class, instead of the cotton roboza, wear a shawl, usually black; and the members of this class will not mix with the lower class. The girls in this class work sometimes in factories managed by Northerners at drawn work; some doing it at home, others in the shops, at so much per day. The former go to the factory; get their bundle (a foot long by three inches in diameter) to take home; but so proud are they that they hire a peon to carry it home for a cent or two.

Oil is a great necessity both for light and fuel; but they cannot buy it for any reasonable figure; there is the duty in the first place to pay (a difference in the standard money of more than double), then the risk that has to be taken on it; so that it takes three times the value of the produce to buy it in Mexico, and they must have these outside products. Could a man live on the products of Mexico, he would live very cheaply; but he must have outside products for comfort. Until very lately the products of Mexico were the same, silver bought as much as it ever did; but this last sharp decline in silver has broken the camel's back, and now silver does not buy as much as it ever did and the cost of living has increased, without an increase in the wages, and the excuse the ordinary salesman will make for charging a higher price in Mexico is, as he says, the change in the price of silver.

The burro is the great institution of the country. He will carry more than his own weight and carry it till he drops. The transportation question is being settled now by the railroads being built under a government subvention of from $6,500 to $9,500 per kilometer, about one-fourth of the cost of the railroad, and that is paid in revenue bonds, and six per cent. of the customs duties must be set aside to redeem these bonds. The engineer has charge of the train, while the conductor is a Mexican. But the engine driver runs when he is ready, and not before. Coffee in sacks costs 3 cents per pound additional for transportation 40 miles off the line of the railway and is worth nothing at the distance of 120 miles. The culture of the grape and the silkworm culture was introduced by a reformer in 1810; but the Spanish government wanted to keep the revenue of the colony and so it destroyed all the vines, silk and mulberry trees; and that was part of the many difficulties which led to the rebellion which finally expelled the Spaniards from the country. There are a good many forms of sisal fiber, all coming from a species of maguey, Agave Americana is one particular form from which sisal is made. The Mexican hammocks, coming from Yucatan, are made from sisal. There is another form called henequin; another fiber from the banana leaf, all kinds of articles are made from it; rope, brushes, shoes, bags, fans, carpets, saddles, hats, everything, fibers for ladies' corsets in this country. The straw is thrashed by trampling out by the feet of oxen. Our modern thrashing machine has been introduced; but it is not popular, it makes too much work; it leaves the straw whole. The Mexican wants the straw all broken up by the same thing that gets the grain out, so that it is ready to feed to the cattle. Labor is cheaper than lumber in the country; and that is particularly shown in the way they weigh commodities. Instead of putting up a wooden spar to hold a cross beam, from which the scales may be suspended, they will walk two men around all day with one beam on their shoulders. Whenever an article is to be weighed, these men take the beam and put it across their shoulders and thus become a part of the scale. The Mexican burro owner is very tender of his pets, cats and domestic animals, but not of his beasts of burden; he never hesitates to get on top of a burro, no matter how heavily he is laden. The man rides the burro; his wife walks behind; and if there is anything to carry, his wife carries it. When a company of soldiers moves from one post to another, there is a company of wives following after, and the government recognizes it; because they virtually act as a commissary, and the government does not have to cook for the troops. The priests introduced the burro as an animal to relieve the overworked laboring man, or in the interests of humanity; but the porters, preceding the burro, opposed it as a labor-saving device calculated to prevent them from earning a living. The peon is opposed to improvements, machinery or anything else; and they will carry these big loads in preference to giving them to a burro, carrying, in some cases, 150 pounds 20 miles daily.

At death, Mexicans, unless very wealthy, are put in little pigeon holes formed in masonry above ground, for seven years, and the rental must be paid in advance. W[illegible] the term has expired, the body will be [illegible] ess the rent be again paid. The body dries up in that rarefied air, and, if taken out, is set up against the side of the vault.

Guadalajara is noted for its pottery works. The market place for pottery or any other kind of work is best seen on the universal market day—Sunday. When the fashionable are at church, all the rest of the country is at market. It is a very wealthy town of some forty-seven millionaires. All business stops at midday for at least two hours; all the tramcars stop; all the building operations stop; the post office closes; you cannot get a letter. It is troublesome in most towns to get a letter. You used to have to wait until the list of all the received letters was posted on the outside of the office. In all but the city of Mexico every post office closes for two hours in the middle of the day and everything stops on account of the intensity of the heat. You will feel cold when the sun is off on account of the altitude. The difference between the sun and shade is the difference between 90° and 70°; and the difference between day time and night time is the difference between 70° and 40°.

THE CALCIUM CARBIDE INDUSTRY.

CALCIUM carbide and acetylene gas still continue to rival bicycles and incandescence mantles in their attractions for the genus "inventor" of this and other countries. In the first half of the present year there were no less than 117 applications for patents dealing with the apparatus for the production or utilization of calcium carbide and acetylene gas; and the total number of applications for patents in the present year will, therefore, most probably exceed that of 1896 by at least 50. These numbers must not be taken too seriously. One may very safely assume that at least 300 of the 400 and odd patents which have been granted are absolutely valueless. In Germany, where the validity of patents is settled in the Patent Office, and not in the law courts, as in our own country, a struggle is at present being carried on concerning the validity of the patent covering the production of calcium carbide in the electric furnace. This master patent was granted to Bullier, a French chemist and assistant to the noted Moissan, whose experiments upon the products of high temperature reaction in the electric furnace have become classic. Although the German carbide manufacturers are stated to have entered into treaty for the purchase of this German patent from the syndicate who hold it, the question as to validity is still unsettled.

In view of the large number of patents that exist bearing upon calcium carbide and acetylene, and of the exaggerated ideas that have been fostered concerning the future of the latter as an illuminating agent, it is not surprising that the craze for company promotion which marked the rediscovery of the compound in 1893 has continued during the present year. At least twelve new companies have been registered during the last twelve months, having as their object the production or exploitation of calcium carbide or acetylene gas. The nominal capital of these companies is over £550,000, and it would be exceedingly interesting to know what proportion of this has actually been subscribed by the general public, and also what is the amount of cash that has found its way into the pockets of patentees and company promoters connected with these twelve companies. Of this total, four are in our own country; but, so far as we know, not one of them has started to manufacture carbide.

The number of factories where carbide is at present produced is estimated at seventeen; only one of these is in this country—that owned by the Acetylene Illuminating Company and situated at Foyers, Scotland. Most of these factories are only producing carbide upon a small scale, and in several cases the manufacture is simply a secondary one, taken up temporarily because the price of carbide is still inflated, and the production offers more profit than the ordinary manufactured product of the works. When the industry has settled down on a firmer basis, these factories will, possibly, drop the manufacture. With regard to the output of carbide per electrical horse power day, and to the cost of production, some of the earlier estimates are held to have been too favorable, and it is now believed that the output will not average more than 9 pounds of carbide per electrical horse power day, and that the cost will be about £10 per ton.

Prof. Vivian Lewes has recently stated that at Foyers the average yield is 8·4 pounds per electrical horse power day from a furnace absorbing 1,000 to 1,200 amperes at 60 to 70 volts pressure. With carbide at £10 per ton, acetylene gas will cost about 18s. 8d. per 1,000 cubic feet, without any allowance for the cost of generating and purifying it, and its use as an illuminating agent will be correspondingly limited. M. Patin, of Paris, has recently applied for a patent for a process which is stated to cheapen the production of the carbide, but no details of this process have yet been published.

As regards the use of acetylene or of calcium carbide there is little progress to report. The instances in which acetylene is being regularly used as an illuminant, i. e., other than for experimental or advertising purposes, are very few. The majority of recent patents have related to generators for the production of acetylene gas from calcium carbide. The reaction between the water and the dry calcium carbide is extremely violent, and in one of the earlier forms of generator much advertised and sold, the apparatus on newly charging always produced an escape of gas into the atmosphere. This defect is said to be avoided in some of the later forms. A certain and ready detector for this defect in generators is one's nose; for acetylene rivals sulphureted hydrogen gas in the objectionable character of its odor. A recent patent proposes to avoid this difficulty by casting the carbide into sticks, and by then soaking these in naphtha or in heavy hydrocarbon oils. Acetylene has recently been experimented with as a lighting agent for trains in France and Germany; and it was stated not very long ago that the authorities in the latter country had ordered 20 tons calcium carbide for experimental purposes.

Prof. Vivian Lewes has recently discussed the application of acetylene as a ship's illuminant, and Warren has suggested the use of calcium carbide as a reducing agent in metallurgical operations. By heating together calcium carbide and metallic oxides he has obtained the metals or alloys of the metals with calcium. The present market for carbide is chiefly due to the demand for experimental or advertising purposes, and a legitimate demand for this much boomed product can hardly yet be said to exist.

With regard to the properties of gaseous and liquid acetylene, there have been a considerable number of facts published lately, and some useful information has also been given concerning the precautions which it is necessary to take in dealing with acetylene in either form. A few of the more interesting of these are given below. Acetylene does not combine with the hæmoglobin of the blood. It produces death when inhaled, simply by asphyxiation. If a vessel containing liquid acetylene be allowed to receive a blow, or to fall from a height of 6 meters to the ground, explosion with actual combustion of the acetylene will occur; if, however, the liquid acetylene be detonated by means of an incandescent platinum wire, a mere resolution of the acetylene into its elements, carbon and hydrogen, without combustion, occurs. The pressure generated in the former case is said to be equal to 5,564 atmospheres. If too little water be used in the generators when producing acetylene gas from the carbide, the heat of the reaction between the latter and the water may rise so high that an explosion will occur. The acetylene generated from commercial calcium carbide is always impure, and it should certainly be purified before use, especially if it is to be stored in a gasholder for any length of time. Phosphureted hydrogen, its most dangerous impurity, can be removed by passing the acetylene through scrubbers containing solutions of metallic salts.

Pictet recommends that the gas should be passed successively through calcium chloride solution, a lead salt solution, and sulphuric acid at −16° C., if it is to be compressed or liquefied for storage purposes. A much safer method of storing is, however, to use acetone for absorbing the gas. This chemical absorbs twenty-five times its own volume of acetylene at the normal temperature and pressure, and 300 times its own volume of the gas at a pressure of twelve atmospheres. If acetylene is to be stored in an ordinary gasholder, brine should be used in place of water for sealing the apparatus, since the gas is practically insoluble in the former. Acetylene is inferior to benzine in economy as an enricher of coal gas. The consumptions of acetylene and coal gas per candle power hour in various types of burners are as follows:

Acetylene			0·0227—0·0282 cu. ft.
Coal gas	Non-incandescence burners.	Bat's wing	0·406 "
		Argand	0·353 "
		Siemens	0·130 "
	Incandescence burner.	Auer's	0·095 "

These figures show how remarkably the introduction of incandescence lighting has improved the position of coal gas as an illuminant, and how difficult it will be for acetylene to displace the latter, except in those places where the price of coal gas is abnormally high. The incandescence principle has now been applied successfully to oil lamps. This fact still further handicaps the progress of acetylene as a lighting agent, since it is largely robbed of its most distinctive feature—its brilliancy—by the improvement in gas and oil illumination obtained by the application of the incandescence principle to burners and lamps. The high illuminating power of the acetylene flame is stated to be due to the exceedingly high temperature of the carbon particles: this temperature is believed to be nearly 4,000° C.—Engineering.

LAFCADIO HEARN ON JAPANESE ART.

NUMBER fifteen of the Taiyo contains an article from the pen of Mr. Lafcadio Hearn entitled Nihon Kaiga-ron (Japanese painting), of which we give a short summary. At a meeting of the Japan Society held in London last year, Mr. Edward Strange read a paper on Japanese painting, in which he spoke in laudatory terms of the peculiarities of Japanese art. This evoked a great deal of opposition and a warm discussion ensued. Among other things, it was said that no such woman as is sketched by the Japanese artist was ever seen. The question caused so much excitement that the Japanese minister, Mr. Kato, in order to quiet the feelings of the combatants, turned the discussion into another channel. The objections to Mr. Strange's view were evidently founded on want of initiation into the mysteries of Japanese art. This art requires special study. My own experience was that at first Japanese painting seemed anything but attractive, but after two years' study I began to see something charming in it, and from that time it grew on me until it appeared no other than marvelous. A Japanese studying western art would no doubt undergo a similar experience.

The characteristics of Japanese art which have special merit I will now endeavor to indicate: 1. The relation of individual objects to a given type, the subjection of special characteristics to an all-prevailing nature are invariably observed. By a few clever strokes of the brush an insect or a flower is made at once to declare its identity and to show its relation to the family to which it belongs. Rather than Nature herself, he prefers to embody the idea which she suggests. 2. In Japanese portrait painting. In accordance with that strong national trait which makes the suppression and concealment of emotion meritorious, there is no attempt to represent passing states of feeling. From their pictures it is difficult to decide whether a person is old or young, good or bad, much less the state of feeling of the individual represented. The high regard in which an absolutely passionless state is held may be traced to Buddhism. 3. In ordinary foreign painting great minuteness is aimed at, but the Japanese think more of general effect. Both styles have their advantages, though to carry minuteness to an extreme is considered vulgar even in the West. What are called Ukiyoye convey to my mind a most vivid impression of passing scenes, but this impression is not caused by the faithfulness of these sketches to details—by their reproduction of actually existing objects—but by a certain subtle suggestiveness which they possess. All high class art deals with the ideal rather than the real. The finest productions of Greece were founded on religious, or at any rate on transcendental, conceptions. There is a point where the art that is the result of special study and the art that comes from intuition meet, resulting in the creation of beauty of a very high

order. Both Greek and Japanese fine art alike remind us of the idea of Herbert Spencer's, that expression is form in the process of creation. 4. Greek art and Japanese art have much in common. They both aim at representing objects rather as they should be than as they are. The Greeks expressed their ideas respecting the gods and the aspirations of the human race. The Japanese represent the simple, unsophisticated happiness of beings who live in harmony with nature, but portray also the superiority of self control and observance of the laws that govern society. Modern western art, which is occupied with present modes of life, with the greed of the money seekers, and kindred subjects, is not only far removed from the sublime idealism of the ancient Greek, but is inferior to the Japanese standard. 5. Much depends on the proclivities of the critic in all art criticism. It takes years to become accustomed to an entirely new style. I have often been amused and instructed by listening to the unvarnished opinions of Japanese children in reference to our western pictures. Appreciation of anything valuable in the world of art involves years of laborious study. This fact is constantly overlooked by persons who undertake to pronounce an opinion on oriental art.

STRAIGHTENING A CHURCH SPIRE.

A VERY skillful piece of work has just been executed by a firm of building contractors, Messrs. Hunter & Company, of Belfast, and the details of the feat performed by the firm, viz., straightening en bloc of a church spire in the County Cork, may be of interest. For some time past, says the Irish Times, it had been noticed that the spire of Trinity Church, at Newmarket, County Cork, was considerably out of plumb, and latterly was leaning over to such an extent as to threaten to topple down on the body of the sacred edifice. Such a dangerous state of affairs could not be allowed to continue, and when Colonel and Lady Mary Aldworth returned from abroad they had steps taken immediately to have the matter remedied. This was no light undertaking, as to all appearance the work necessitated the complete taking down and rebuilding of the spire of the church. A skillful architect was engaged to inspect the church tower and spire, after which a contract was entered into with the well-known firm of Hunter & Company, Belfast, to promptly execute the work. Mr. Hunter and his staff of experienced steeple-jacks attended specially from Belfast and set about the work of taking down and rebuilding the spire, but to the surprise of all, they found that the spire could not be taken down except it was done en masse, as the stones of which it is built were hermetically bound to each other with a combination of molten lead and sand which rendered it absolutely impossible to separate one stone from another, the whole spire being, as it were, one solid block. On further and closer inspection it was found that the entire building was erected in a similar manner, no other mortar or binding substance of any kind being used save the sand and molten lead—a very curious and interesting circumstance to note. The most firm and enduring (but at the same time most expensive) form of construction was, it appears, much in use in Ireland over a century ago. A huge iron shaft runs through the top portion of the spire, on which the stones were slipped like rings and irrevocably riveted with lead and sand. Under this extraordinary circumstance the idea of taking down the tower had to be abandoned, as being quite impracticable, if not utterly impossible; but the desired end has been attained in as satisfactory a manner by an ingenious and clever method adopted by the contractor and his staff. The spire has been brought back to its original true perpendicular position, and now tapers beautifully straight, standing out very handsomely, the joints being beautifully pointed with mastic cement.

HOW WORRY AFFECTS THE BRAIN.

MODERN science, says Pharmaceutical Products, has brought to light nothing more curiously interesting than the fact that worry will kill. More remarkable still, it has been able to determine, from recent discoveries, just how worry does kill. It is believed by many scientists who have followed most carefully the growth of the science of brain diseases that scores of the deaths set down to other causes are due to worry, and that alone. The theory is a simple one—so simple that any one can readily understand it. Briefly put, it amounts to this: Worry injures beyond repair certain cells of the brain; and the brain being the nutritive center of the body, the other organs become gradually injured, and when some disease of these organs, or a combination of them, arises, death finally ensues. Thus does worry kill. Insidiously, like many other diseases, it creeps upon the brain in the form of a single, constant, never lost idea; and, as the dropping of water over a period of years will wear a groove in a stone, so does worry gradually, imperceptibly, but no less surely, destroy the brain cells that lead all the rest—that are, so to speak, the commanding officers of mental power, health and motion.

Worry, to make the theory still stronger, is an irritant at certain points, which produces little harm if it comes at intervals or irregularly. Occasional worrying of the system the brain can cope with, but the iteration and reiteration of one idea of a disquieting sort the cells of the brain are not proof against. It is as if the skull were laid bare and the surface of the brain struck lightly with a hammer every few seconds, with mechanical precision, with never a sign of a let-up or the failure of a stroke. Just in this way does the annoying idea, the maddening thought that will not be done away with, strike or fall upon certain nerve cells, never ceasing, and week by week diminishing the vitality of these delicate organisms, so minute that they can only be seen under the microscope.

To Rid Caoutchouc Articles of their Disagreeable Odor.—Most caoutchouc ware has a highly unpleasant odor, which is also imparted to other goods, for which reason such articles cannot be used for many purposes. According to S. Bourne, this smell will entirely disappear, if the articles are covered on both sides with a thin layer of animal charcoal and then heated with the charcoal for 3 to 4 hours from 50° to 60° C.

THE

Scientific American Supplement.

PUBLISHED WEEKLY.

Terms of Subscription, $5 a Year.

Sent by mail, postage prepaid, to subscribers in any part of the United States or Canada. Six dollars a year, sent, prepaid, to any foreign country.

All the back numbers of THE SUPPLEMENT, from the commencement, January 1, 1876, can be had. Price, 10 cents each.

All the back volumes of THE SUPPLEMENT can likewise be supplied. Two volumes are issued yearly. Price of each volume, $2.50 stitched in paper, or $3.50 bound in stiff covers.

COMBINED RATES.—One copy of SCIENTIFIC AMERICAN and one copy of SCIENTIFIC AMERICAN SUPPLEMENT, one year, postpaid, $7.00.

A liberal discount to booksellers, news agents, and canvassers.

APPARATUS FOR DETECTING WITH THE AID OF CROOKES TUBES THE LOCATION OF FOREIGN BODIES.

NEW SYSTEM FOR LOCATING BULLETS.

THE surgeons were the first to comprehend the practical importance of the discovery of the X rays. But a few days elapsed after the never-to-be-forgotten communication by Prof. Roentgen before the hospitals of Paris were using the "radiograph" or the "radioscope" for locating foreign substances introduced into the bones or tissues of human bodies.

But the surgeons were not long in discovering the fact that it was imprudent to exact too much from these rays. They did not always indicate the precise location of these foreign substances, and the operator sometimes risked the patient's life by depending too completely on the insufficient indication given by the X rays.

It was ascertained without a doubt that the radiograph, even with the aid of clinic signs, was manifestly impotent—this fact has been proved by repeated experiments—to positively locate a ball which had been fired into the brain by a murderer's or suicide's hand.

FINDING THE DIRECTION OF THE BALL WITH THE COMPASS.

Was it possible that this collaboration with the X rays, from which so much had been hoped, would prove a failure? Surgeons had been forced to this conclusion much against their will, when, fortunately, a young man, M. Contremoulins, of the Laboratory of Micro-Photography, under the direction of M. Remy, member of the Faculty of Medicine, in Paris, came to the fore and quieted the fears of scientists and surgeons by inventing an apparatus called "le chercheur de projectiles," or "searcher for projectiles," which he claims is capable of revealing with the absolute precision of a "demi-millimeter" the exact location of a ball in the brain.

This apparatus, which only left the hands of its inventor a few days ago, has a history connected with it which is worth relating. Its invention not only does honor to the knowledge and tenacity of MM. Contremoulins and Remy, but it also proves that there are still some persons in France interested enough in scientific research to encourage them and to help financially when such assistance has been denied by the state.

The Faculty of Medicine in Paris was not in possession of the necessary funds for starting and maintaining a radiograph laboratory, and yet such a laboratory exists and owes its existence to MM. Contremoulins and Remy. The former, fascinated by Roentgen's discovery, and foreseeing its innumerable applications to surgery, procured, at his own expense, with the assistance of M. Remy, the indispensable apparatus for such a laboratory.

He constructed at his own expense an apparatus still embryonic, but which, however, indicated and discovered with a perfect precision any projectile introduced into a brain.

This experiment, first satisfactorily performed some six months ago, was most eulogistically spoken of by Prof. Marey, in a lecture at the Academy of Medicine.

It now became a question of constructing the apparatus of which M. Contremoulins had made the model. This called for an outlay of 2,500 francs. This amount not forthcoming, the construction of this useful apparatus would be retarded and even prevented. M. Marey made this "sad revelation," as he called it, publicly, expressing the hope that in showing the penury to which science was reduced some generous patron might be induced to come foward and donate the necessary sum.

This appeal was inserted in Le Temps, and the next day a M. Dessaux sent the necessary 2,500 francs to M. Marey. M. Contremoulins was then in a position to push the work ahead on his apparatus, which was delivered to him in its perfected state the first of last month.

M. Contremoulins' "searcher for projectiles" has made good its promises. It has already searched for and found the balls which two unfortunates had lodged in their brains. The operation of extracting them was performed recently by M. Remy in a remarkably skillful manner. The patients, who have recovered very rapidly, left the hospital the past week. The success of the operation was proclaimed amid great applause on Monday, December 6, at the Academy of Sciences, and on Tuesday, December 7, at the Academy of Medicine.

The principle of the method is as follows: With the aid of two radiographic proofs, obtained at different times, of a head, inside of which is seen a ball, the center of this ball is determined by a geometrical construction, and by its relation to three fixed points or guiding marks traced on the face of the wounded man.

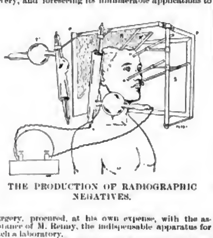
Then, by means of small movable arms jutting outward, the ends of which come together, the relative position of the three fixed points and the ball are determined. The four extremities of these movable arms are then attached to a compass. This compass, thus set, is placed upon the head of the patient and adjusted to the three guide marks on the patient's face; the extremities of the fourth arm, if the head has been perforated, will coincide exactly with the center of the ball. It is then only necessary for the purpose of extraction to follow the direction indicated by the fourth arm and to penetrate to the depth indicated by the length of this arm.

To obtain two radiographic proofs which will permit of the exact locating of the center of the ball calls for the absolute immobility of the Crookes tubes in connection with the sensitive plates. With this end in view, two small, thin pieces of wood are sealed in plaster and placed on the upper part of the patient's head, and to these is screwed a metal plate.

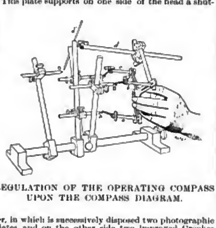
This plate supports on one side of the head a shutter, in which is successively disposed two photographic plates, and on the other side two improved Crookes tubes, joined in such a manner as to allow them to be moved to any desired position.

Besides, this metal plate has on its outer surface three jointed arms, whose extremities are placed on the three guide marks on the patient's face; these marks are, generally, one on the forehead and two on the cheeks. This primary apparatus being thus disposed (and called the "searching apparatus"), a photographic plate is slid into the shutter, and is worked by sending a current from a very powerful Ruhmkorff coil, giving a thirty-eight centimeter spark through one of the Crookes tubes.

At the end of a quarter of an hour a radiograph is obtained. After this plate is developed, the shadow of the ball will be distinctly seen in the interior of the brain. The operation is renewed by means of a second plate and a second Crookes tube. In this way two pictures of the same ball are obtained, occupying different positions, for the reason that the luminous focus of the two Crookes tubes occupies different positions in relation to the ball and the shutter inclosing the plates.



THE PRODUCTION OF RADIOGRAPHIC NEGATIVES.



REGULATION OF THE OPERATING COMPASS UPON THE COMPASS DIAGRAM.

The metal plate is then removed from the patient's head without disturbing the different parts of the apparatus. If we now prolong the focus of each of the Crookes tubes and the center of the shadow of the ball on the corresponding radiographic plates by means of threads, we reconstruct the path of the luminous rays. The point at which these threads cross is the point at which the luminous rays had but a moment before met. This, then, is the center of the ball, and the point at which the threads intersect each other gives the exact position of the ball in the brain at the moment the radiograph was taken. This apparatus M. Contremoulins calls "the compass schema," and by it regulates the compass of operation.

The obtaining of the radiographic negatives that permit of determining the center of the ball necessitates an absolute immobility of the Crookes tube with respect to the sensitized plates. To this effect, two pieces of wood, R R, to which is screwed a metallic frame, P, are fixed to the head of the patient with plaster. This frame, on one side of the head, supports a frame in which are successively arranged two photographic plates, S, and, on the other side, two improved Crookes tubes, T and T', so jointed as to permit of giving every position necessary. Besides the frame, P, carries at the front part three jointed rods, the extremities of which are applied to three points of the patient's face, which are usually selected as follows: One upon the forehead, M, and the two others upon the cheek bones, N O.

This first apparatus, called the "research apparatus," being thus arranged, a photographic plate is placed in the frame, and one of the Crookes tubes, T, is actuated by passing through it a current from a very powerful Ruhmkorff coil, giving a 38 cm. spark. At the end of a quarter of an hour the radiograph is obtained. Then the plate is developed, and the image of the projectile is seen detaching itself from the interior of the image of the skull. The operation is renewed with a second plate and the second Crookes tube. There are thus obtained two images in which the projectile does not occupy the same place, since the luminous foci of the two Crookes tubes occupied different positions with respect to the ball and to the frame inclosing the plates.

The frame, P, is removed without touching the different parts of the apparatus. If we connect by wires the focus of each of the Crookes tubes with the center of the image of the ball upon the corresponding radiographic negative, we shall reconstruct the passage of the luminous rays. The point at which these wires cross each other is the one at which the luminous rays were just met with. It is therefore the center of the ball; and the point of intersection of the wires gives the position that the projectile occupied in the skull at the moment at which it was radiographed. The three rods, whose extremities, M N O, correspond to the three register marks of the face, remaining in place, the crossing point of the wires gives the position of the center of the ball with respect to the three register marks. The whole of this permits of the construction of a diagram practically fixing the relative positions of the projectile and the three register marks.

Near the apparatus above described is placed a small platform on which slide four columns carrying four jointed rods. It suffices to bring the extremities of these rods in contact with the crossing point of the wires and the register points, M N O, in order to transfer to D the center of the ball and to A B C the register points, in their relative positions. This is what M. Contremoulins calls the compass diagram.

Henceforward the primitive apparatus will be useless. The diagram will advantageously replace it, since it is possible to pack it and carry it to a hospital or to the home of the patient.

The "compass operation" is, properly speaking, the true "projectile seeker." This compass consists of four branches, three of which, a b c, are so fixed and arranged as to apply themselves by their extremity to the points, A B C, of the compass diagram, which correspond to the register points of the patient's face. The fourth branch, d, which is movable in all directions, carries a guide through which slides a blunt needle, d'. This branch is fixed in the proper position and the needle is made to slide until it comes into contact with the point, D, of the rod of the compass diagram representing the center of the projectile; and by means of a screw ring one fixes upon the needle the point at which it stops in the guide when its extremity is in contact with the point, D.

The operating compass is regulated, and all that remains to be done is to transfer it to the patient in order that the surgeon, guided by the needle, may begin his work. In order to effect this transfer, the blunt needle is removed from its guide. As shown in the figure, the extremities of the three branches, a, b, c, are applied to the three register marks tattooed in the patient's skin. Then it suffices to slide the needle in its guide in order to obtain a precise indication of the direction in which the ball is to be found. The depth is indicated by the distance between the guide and the ring screwed upon the needle.

As the branch, d, may be placed in any position at will, it suffices to regulate the compass differently in order to obtain a different direction of the needle. Thus the least perilous, surest and shortest way may be chosen. Whatever be the way selected, the needle will always indicate the exact direction and depth of the projectile. In the course of the operation, the needle will constantly indicate, through the distance of the ring in the slide, the precise distance at which the operator is from the projectile. Finally, when the ring is in contact with the slide, the projectile will be under the surgeon's instrument. If, instead of one ball, it is necessary to extract several, or several fragments, the method may be applied with the same sureness.

For our engravings we are indebted to L'Illustration.

To Make Labels Adhere on Tin.—Labels will adhere perfectly to tin, no matter what paste is used, if you wipe the entire surface of the tin with merely a suspicion of hydrochloric acid. The reason is that all tin is dressed in oil, and hydrochloric acid removes that, just as it does for the solderer.

PINEAPPLE FIBER.

INDICATIONS are that the fiber of the pineapple leaf will eventually take prominent place among the constituents of textile fabrics.

Both the wild and cultivated pineapple yield fiber which, when spun, surpasses in strength, fineness and luster those obtained from flax; can be employed as a substitute for silk, and as a material for mixing with wool or cotton. Useful for cordage, textile fabrics, sewing silk or twist, laces, etc. In China, fabrics for clothing for agriculturists. In request in India as material for stringing necklaces. Produces the celebrated pina cloth of the Philippine Islands. It is remarkably durable, and unaffected by immersion in water; and is white, soft, silky, flexible, and long in staple. Samples cleaned, without washing, in the government experiments in Florida, 1892, when twisted to the size of binding twine, showed a breaking strain of 150 pounds. Dr. Taylor subdivided a specimen of this fiber to one ten-thousandth of an inch.

Pineapple culture, for its fruit, in Florida, is a comparatively recent industry, the first plantings having been made on the keys about 1886, though the first plantation of commercial importance was not established until five years later, on the Indian River. The value of the fiber has long been known, however, and in 1891 the fiber expert of the United States Department of Agriculture began a series of investigations into the practicability of utilizing the Florida leaves for fiber after the fruit had been gathered, as their utilization would give to the United States a new industry. In the experiments of 1892 it was shown that the yield of fiber from freshly cut pineapple leaves ranges from 45 to 60 pounds per ton of 2,240 pounds of leaves. An important point to be noted is the fact that selected leaves as to size do not give as high a yield of fiber as average leaves. Lot No. 1 was 820 pounds of average and 202 pounds of leaves. While the total, 1,022 pounds of leaves, gave 25 pounds of fiber, against a yield of four pounds from 202 pounds of selected leaves. Reduced to equivalents, the average leaves yielded at the rate of 57½ pounds to the ton, while the selected leaves yielded less than 44¾ pounds of fiber to the ton.

Lot No. 5 was from Fuzzard's plantation, near the Perrine grant, 1,000 pounds of leaves, tips cut off. The leaves averaged 10 to the pound. Dry fiber from this 1,000 pounds weighed 18 pounds 2 ounces, or a little over 40 pounds to the ton of leaves. It should also be noted that there was an excessive waste of fiber in the process of cleaning.

Special Agent Monroe, who attended to the details of the experimental work of 1892 in Florida, stated that the practice has been to allow the leaves to decay under the plant and afford possible nourishment to the young suckers. The general opinion on this point is in favor of cutting the leaves, but experiments covering several seasons will be necessary to decide this point. Owing to the practice on the keys of planting very close, it was found that a large proportion of the leaves were injured by chafing one on another, and also from being crushed under foot in weeding and cutting the fruit. This condition seems to be almost entirely obviated by spacing the plants at least two feet, as has been done on the mainland. Another defect was found in the withered condition of several inches of the tip or end, not noticeable in the younger leaves. This, however, may have been due to the excessive drought of the season. It does not occasion much loss of fiber, but adds to the cost of extraction, the decayed parts having to be cut off. The approximate acreage in pineapples in 1892 on keys Metacumba, Largo and Elliott's was 930, and the number of apples shipped (1892) about 1,016,000, which did not include many thousands marketed after the close of the season.

The average yield of good leaves from the Red Spanish was about 10 out of the average 25 of each plant, and the weight one pound, making the total for fruited plants, in round numbers, 938 tons. Adding the leaves to be secured after the close of the season and from abandoned fields, the quantity might be raised to 1,000 or 1,100 tons. This refers, of course, to extreme southern Florida, no account having been taken of the large acreage on Indian River and elsewhere.

As to the value of the fiber, a London quotation for a lot of well cleaned from an Asiatic source was $150 per ton. There is no doubt that if the fiber could be produced in quantity at an economical cost, manufacturers would soon find a use for it and would know what price they could afford to pay for it. The market price would then be fixed by the demand and supply. The machine question enters largely into the problem, however, and as the leaves are small, a quantity would need to be cleaned at one feeding of the machine to make it pay. Estimating ten leaves to the pound, there would be over 22,000 leaves to the ton, which, as we have seen, would produce from 50 to 60 pounds of fiber.

The machine used in the department experiments produced a fine product, but in too small quantity to be employed commercially. There is no doubt that a modified Sisal hemp machine (automatic) would do the work, although a machine has recently been constructed for a small leaved plant that may be adopted to use in extracting the fiber.

The Chinese extract the fiber by hand. The first step is the removal of the fleshy sides of the leaf. A man sitting astride a narrow stool extends on it in front of him a single leaf, one end of which is held beneath him. He then, with a kind of two handled bamboo plane, removes the succulent matter. Another man receives the leaves as they are planed, and with his thumb nail loosens the fibers about the middle of the le... gat...ers them in his hand, and by one effort deta... from the outer skin. ...e fiber is manufactured into a strong, ... resembling the coarser kinds of grass ... Formosa its chief use is for the inner gar... the agricultural class. The fabric is called Huang-li-Pu. Pina is considered to be more delicate in texture than any other known to the vegetable kingdom. It is woven from the untwisted fibers of the pineapple leaf after reducing them to extreme fineness and after the ends have been glued together to form a continuous thread. There is another delicate fabric, used for ladies' dresses, which is said to be manufactured from pineapple fiber woven with silk, the latter forming lustrous stripes in soft colors or shades.

The pineapple cloth of the Philippines is produced by the common pineapple also, i. e., Ananas sativa. The plants have become almost wild in Singapore and the Philippines, with leaves five to six feet long. The fruit is small, but the leaves appear to yield better fiber than the cultivated plants.—From Catalogue of Useful Fiber Plants of the World, by United States Department of Agriculture.

REPEATING BELLS IN CLOCKS.

IT may prove interesting and useful at a given moment to have the striking train of a clock repeat the hour at one's will. We shall describe a simple arrangement devised to this effect by M. F. Derry. This system, which possesses no complicated mechanism, may be applied to any kind of a clock and be actuated at a distance by means of a pneumatic or electric button.

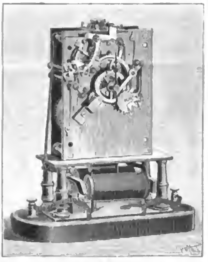

FIG. 1.—A REPEATING CLOCK.

Let us in the first place give a brief description of the classic system of starting gear of a rack train that strikes the hours and half hours. At rest, the different parts are in the position shown in the diagram (Fig. 2), and the wheelwork is arrested by a snug fixed to the piece, H. Upon the piece, A, are fixed two pins, A' and A'', which are so arranged that after lifting the detent, G, the latter may drop just at the moment at which the hour hand is upon 12 or 6. As soon as it is raised, the detent, G, carries along with it the stop, H. At this moment there occurs the first start of the wheelwork, which is almost immediately arrested by a

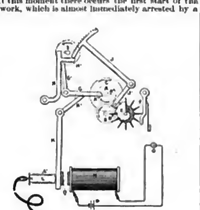

FIG. 2.—DIAGRAM EXPLANATORY OF THE STARTING ARRANGEMENT OF A STRIKING TRAIN.

snug fixed to the detent, G. The object of such start is to render the wheelwork dependent upon the detent, the wheelwork not being set free until the moment at which the detent falls. The pieces, G H, continuing to rise (carried along by the pin, A), the rack, J, soon becomes free, and, actuated by a spring, falls until its arm, J', abuts against the snail, E, leaving beneath the arm, H', a number of teeth exactly corresponding to the indication of the hour given by the small hand.

The snail, E, and the star wheel, D, are interdependent, and the latter, being every hour carried along by the pin, B, advances one tooth and thus permits the rack, J, to make a longer travel in measure as 12 o'clock is approached. The pieces remain in the position just indicated until, the long hand having reached 12, the detent, G, falls and sets the wheelwork free. The piece, H, remains raised (the arm, H', engaging with the teeth of the rack) and permits the wheelwork to continue its revolution. The rack is raised tooth by tooth by the click, I, fixed upon the second wheel. To every revolution of the latter there corresponds one blow struck upon the bell of the clock. As soon as the rack is lifted high enough, the piece, H, falls to its position of arrest in stopping the wheelwork. In order to cause one stroke only to be given at the half hour, the pin, A', is fixed upon a smaller diameter, so as to raise the pieces, G and H, sufficiently to permit of the first start, but not enough to cause the rack to fall. The wheelwork is therefore arrested as soon as the second wheel has made one revolution.

In order to cause the clock to strike at every quarter, the principle is the same as for the hours.

From what precedes it will be seen that in order to free the striking train, it is necessary to raise the piece, H, sufficiently to permit the rack, J, to fall. This is effected by M. Derry's arrangement in a very simple manner. K is a lever, of which the upper arm, K, engages with the detent, G, the lower arm serving for the maneuvering. If the lower arm be provided with an armature, Q, the latter will be attracted by the electromagnet, N, as soon as the circuit of the battery, P, is closed at any point whatever by means of a temporary contact.

The result will be the same if, instead of the electric system, the pneumatic be employed. The arrangement in this case is of still greater simplicity, because it necessitates no installation, either of a battery or of wiring for leading a current from a distributing line.

Two tubes, L and L', one entering the other, are closed at their extremities. One of these tubes is stationary and receives the extremity of a small rubber tube of sufficient length to answer the requirements that one has in view. The other tube is movable and abuts against the lower arm of the lever. Upon squeezing a bulb fixed to the free extremity of the rubber tube a pressure of air will be brought about in the tube, L, sufficient to act upon the tube, L', and, at the same time, upon the lever, K.

Fig. 1 represents what is called a traveling clock, the case and dial of which have been removed.

For the sake of demonstration, both the electric and pneumatic systems above described have been applied to this clock, which repeats the hour at every quarter.—La Nature.

TESTING A BOILER TO DESTRUCTION.

AT the recent convention of the American Boiler Manufacturers' Association, held in Philadelphia, John O'Brien described, says the Mining and Scientific Press, the testing of a boiler to destruction. The boiler was made and the tests were instituted and carried through by the O'Brien Company. The boiler was 60 inches in diameter by 12 feet in length. The shell was ⅜ inch steel of 60,000 pounds tensile strength. The heads were of ½-inch steel. There were fifty six 3½-inch tubes. The front head was braced with five ⅝ by 4 inch flat stays, doubled. The boiler was made of two rings, designated A and B. The joint of ring A was a butt joint with inside and outside straps. The joint of B was a triple rivet lap joint, with an inside strap extending 2½ inches each side of the ends of lapped plates. The circular seams were single riveted.

The results of the tests, in which hydraulic pressure was employed, are indicated by the following record:

TEST NO. 1.—MARCH 29, 1897.

Ring B.

	Inches.
At 300 pounds pressure ring expanded	1⅝
" 450 " " " "	2⅝
" 750 " " " "	3⅛

Ring A.

At 300 pounds pressure ring expanded	2⅝
" 450 " " " "	3½
" 750 " " " "	5

TEST NO. 2.—APRIL 4, 1897.

Ring B.

At 625 pounds pressure ring expanded	3⅜
Increase in expansion over test No. 1	⅝

Ring A.

At 625 pounds pressure ring expanded	5¼
Increase in expansion over test No. 1	¼

TEST NO. 3.—APRIL 5, 1897.

Ring B.

At 350 pounds pressure ring expanded	4 1/16
" 400 " " " "	4 1/16
" 625 " " " "	4 7/16
Increase in expansion over test No. 2	1/16
Total expansion for the three tests	4 7/16

Ring A.

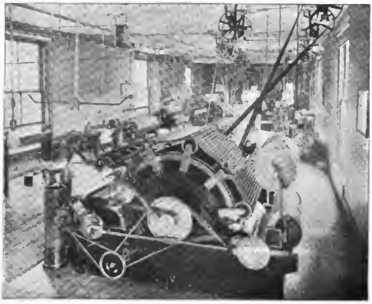
At 350 pounds pressure ring expanded	5⅜
" 400 " " " "	5½
After 400 pounds pressure no perceptible change occurred.	
Increase in expansion over test No. 2	⅛
Total expansion for the three tests	5½

At 900 pounds pressure the boiler ruptured on the side, horizontally in the second ring about 18 inches above the riveted joint, in the whole plate, the rupture being about a foot long.

The putting of new wine into old bottles is by no means an uncommon occurrence in these degenerate days, says the Pottery Gazette. An ingenious inventor, however, has devised a bottle which cannot be refilled without detection. It has a visible compartment, in which is placed blotting paper or some other substance which will be defaced by wetting, and is so constructed that, in pouring into it, some of the liquid must enter the compartment.

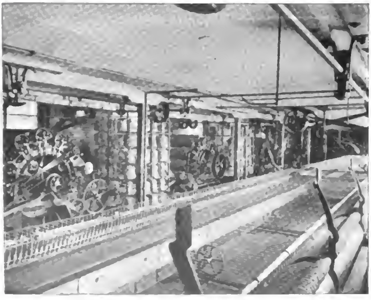
PHILADELPHIA TEXTILE SCHOOL.

WE take pleasure in publishing in the present issue a few views of the Philadelphia Textile School, an institution which is destined to exercise a powerful influence in the development of American manufactures. The question of technical education has come to be regarded as of the very first importance in the industries of this country, and it may be safely stated that on nothing else does their future welfare depend quite as directly as on the promotion of such good work as that of which the Philadelphia Textile School is the leader in America. The eagerness with which the establishment of similar schools is discussed throughout the South and the recent establishment of a school in Massachusetts furnish sufficient proof of the fact that this principle is now recognized, and the work of educational organization and adjustment which it implies is sure to go rapidly forward after this.



A VIEW IN THE COTTON CARDING AND SPINNING ROOM OF THE PHILADELPHIA TEXTILE SCHOOL.

ONE OF THE POWER WEAVE ROOMS.



THE WOOL CARDING AND SPINNING ROOM.

The school, which is a part of the Pennsylvania Museum and School of Industrial Art, is simply the embodiment of the idea that technical education, to be effective, must be definite and practical in its relation to the industries which it is intended to affect. It is not a school for the teaching of the general principles of mechanics or of anything else. Its laboratories are practical workshops, or rather mills, in which the greatest variety of production is carried on, and may be studied and practiced almost as well as in establishments devoted to any one line of manufacture and managed on a commercial basis. It is well known that while there are excellent schools of this kind in Europe, there are very few in America. We have illustrated the Lowell Textile School in the SCIENTIFIC AMERICAN for October 16, 1897. For example, the very excellent school at Crefeld, which is always pointed to as probably the best school of its kind in Europe, while well equipped for the study of silk, is by no means fitted to teach the principles that relate to cotton manufacture. The school in Manchester, England, has excellent facilities for teaching the manipulation of cotton, but is meagerly provided with either appliances or courses for the instruction of whatever relates to wool or silk.

The Philadelphia Textile School, enjoying as it does the advantage of being located in a city whose textile industries are not only enormously developed, but immensely varied, and having students interested in the greatest variety of work, has the opportunity of illustrating its teaching outside of the class room by means of visits to the industrial establishments of almost every conceivable form of textile manufacture in the neighborhood. The managers of the institution have always aimed to make the most of these advantages, and alike in the selection of the equipment and of the instructors, they have aimed to give the utmost possible breadth to its work.

The school is magnificently housed in buildings that stretch the entire length of a Philadelphia square in the very heart of the city, and is furnished with every kind of material which is requisite to the treatment of fibers, from the raw material to the finished fabric; including chemical laboratories, a dye house, carding and spinning rooms for wool and cotton, as well as appliances for the reeling of silk, etc.

The corner stone of its system, so far as the methods of instruction are concerned, is insistence upon the thoroughness with which each student is expected to perform the practical work instead of having all the hard work done for him, as is almost universally the case in European schools of a similar character. This is a thing which is at once recognized and commented upon by visitors and students who have attended the schools in Europe, of which there have been a great many registered in the Philadelphia Textile School. They unhesitatingly testify to the superiority of the American method and bear testimony to the fact that it is in the main a great mistake to send boys to Europe for an education of which they are expected to apply the results in America.

In the Philadelphia school every boy is expected to dye his own yarn, make his own warp, punch his own cards, and weave his own goods, and for this purpose a loom is assigned to him and he alone is responsible for what it contains and what it produces. This is probably not the case in any school in Europe, or any other in America, where mechanical appliances are for the most part used more for demonstration of principles and theories than as a means of manual as well as mental development. The importance of this principle is hardly to be overestimated; if the new idea in education means anything, it means that the pupil learns by doing. Laboratory methods are not merely demonstrations. If they were, the lecturer with a perfectly equipped desk between him and his pupils would furnish the ideal of teaching. The Philadelphia school carries the laboratory idea further than any institution in our midst, and the boys actually do the work, thereby being educated and developed. Not the least important thing that is to be said about this new education is that it has caused a class of men to take a deep interest in educational matters who used to think very little about them. Delegation after delegation of business men have visited the Philadelphia Textile School and have borne testimony to the importance of the work in which it is engaged.

The New England Cotton Manufacturers' Association, a body which had never held a meeting outside of New England, with the exception of the one held during the Atlanta Exposition, held its last convention in Philadelphia, in order that its members might inspect the work of the Philadelphia Textile School.

The National Association of Manufacturers also held its annual convention in Philadelphia in June, 1897, and devoted a portion of its time to the inspection of the school, when President McKinley visited the school and spoke in the highest terms of the work which it was doing and the important influence which it was sure to exercise on the industrial development of the country.

The interest manifested by the National Association of Manufacturers is of exceptional importance from the fact that the present president, Mr. Theodore C. Search, is the man to whom the school really owes its creation. Early in the eighties, Mr. Search, through his own initiative, and with only a meager support, established the school in the conviction that it was the one thing necessary for American textile progress, and almost unaided for many years he carried on the noble work of building up the institution which enjoys so great a reputation to-day.

FIRST PEANUT OIL FACTORY IN THE UNITED STATES.

THE first peanut oil factory in the United States will be established in Norfolk, Va., at an early date. The oil is highly valued in Europe, as it is stated that fully \$3,000,000 worth of peanuts are taken into Marseilles annually for the manufacture of oil, which is used in

toilet soaps and for other purposes. The peanut flour is quite extensively used in Europe and made into bread, cakes, biscuits, etc. It is one of the favorite articles of food, according to consular reports, in hospitals in Germany. The capital stock of the peanut company is $00,000, and it will operate under the patents of Mr. Weatherly, which cover the machinery and methods of decorticating the kernel of the inner skin. According to the estimates made, says the Atlanta Constitution, the cost of a plant for treating five tons of peanuts daily is as follows: Machinery, $0,000; building, $0,000; while the expenditures, including labor, insurance and taxes, amount to $857 per day. In a prospectus issued by the company, it is calculated that the receipts from five tons of peanuts will amount to 285 gallons of refined oil at $1 per gallon, 175 gallons of crude oil at 50 cents, 3,680 pounds of flour and meal at 2 cents and 3,680 pounds of stock feed at 60 cents per 100 pounds, making the total gross receipts $415.90 per day, which, it is estimated, would give a yearly profit on a five ton factory of $19,735.—National Provisioner.

ENLARGEMENT OF THE PORT OF MARSEILLES.

A DECREE of July 17, 1893, declared of public utility the work to be executed for the enlargement of the port of Marseilles through the construction of a new basin to the north of what is called the National. As this maritime work has just been begun, we think that we shall interest our readers in making known to them the reasons that prompted it and the conditions under which it is proceeding.

Despite the great injury to the exterior commerce of France caused by the successive increases in customs duties, the increase of navigation in the port of Marseilles rendered a new extension of the basins necessary. In fact, while in 1878 the total figure of the tonnage gage of the vessels that entered and cleared was 5,400,000, it rose in 1889 to 9,518,300, and in 1891 to 10,611,000, with a drop to 9,453,000 in 1893, followed in 1896 by a rise of 10,548,000 tons divided among 16,290 ships.

Unfortunately, it must be considered that such increase is due especially to foreign flags and that it is very slight as compared with the progression followed by the large competing ports.

On comparing the effective movement per linear foot of wharf (that is to say, the quotient of the tonnage gage by the utilizable length of the wharves) with the figure of 300 tons considered as the limit beyond which maritime commerce ceases to have the facilities of which there is need, we clearly recognize the inadequacy of the present installations of the port of Marseilles, since the normal coefficient was doubled in 1896. The wharves that are particularly needed are such as may be accessible to ships of heavy draught.

There is no wharf that can receive vessels drawing more than 25 feet of water, and these have to operate in the middle of the basins. As the Suez Canal has been deepened to 28 feet, it became urgent to provide for the landing of vessels of such load water line at wharves. The work of deepening the National Basins along the wharves of its two inner moles is now in progress.

The creation of a new basin was further prompted by the removal toward the north of the New Abattoir ... which it appeared expedient ... landing of cattle, of which ... Finally, a special ... petroleum has long ... utmost necessity, in order to prevent ... fire in the port and to isolate the ... entrance to which will be closed by ... vel of the sea.

The arrangement of the places ... made up to the present to the extension of ... illes toward the north and also the pros... of the junction canal with the Rho... ated the general plan of the new basin, con... olonging the jetty (which is already 2½ ... gth) in a straight line to abreast of Cape ... in constructing the new maritime ... etween it and the shore. The new basin, called the "Pinède," after the name of the cape in front of which it will extend, will measure 2,100 feet in length by 1,640 in width. It will be divided into three secondary basins by two moles and be bounded on the north by the mole of Madrague, situated in front of the village of that name, which has become a faubourg of Marseilles.

The Pinède basin will increase the length of the utilizable wharves in the interior of the port by 9,050 feet, a length which now reaches the total figure of 43,285 feet for a surface of water of about 1,300,000 square yards. The depth at the foot of the new wharves will be everywhere 28 feet. Moreover, the alignment of the shore wharf prolonged beyond the petroleum yard as far as to Cape Janet will unite in Madrague Bay a surface of about 120,000 square yards, which will form an excellent docking for the numerous ships, lighters, etc., that encumber the different basins.

The plans (Figs. 2 and 3) of the port of Marseilles and of the new basin that is to be opened to the north will permit of obtaining an accurate idea of the work that is now in progress. All the plans and specifications having been definitely drawn and the arrangements made by the maritime engineering service, which is under the direction of M. Guerard, the work was begun and then suspended and last year was made the object of a new adjudication, comprising the construction of wharf walls and the deepening of the basin. Out of the four houses that put in bids, that of Zschokke, of Switzerland, which has done much work in France, obtained the contract at five million francs, the work to be completed in five years.

At the beginning of June last, work was begun in front of Cape Pinède by the construction of a wharf wall, which will form the north side of mole E.

Two large compressed air caissons of an improved type were submerged. In each of these 20 laborers work at a time, at a depth which is 20 feet at present, but which will be increased later on, since the walls of the batterdeaus will have to be founded at 40 feet below low tide. Four other caissons will successively be put in service in measure as they are needed.

The arrangement and installation of one of these caissons present considerable interest and are worthy of description. The caisson consists of a large rectangular iron plate box 65 feet in length, 21 feet in width and 9 feet in height. There is no floor, but, on the contrary, the ceiling, which is situated at a height of 6 feet, is of double thickness and strengthened by very strong iron girders. The walls of this huge caisson rest through their sharp edge upon the rocks of the uneven bottom of the sea, and the working chamber has a capacity of 2,800 cubic meters.

The caisson is kept perfectly tight by means of compressed air. The high pressure of the air prevents the ingress of water from below, and on another hand, the ballast deposited upon the top and kept in place by the rim of the caisson prevents the latter from rising.

Communication between the exterior and the interior of the caisson is assured by three cylinders wider than the diameter of the human body and of variable height and that emerge above the level of the sea, where each terminates in an air lock. One of these locks serves for the workmen and the two others for the materials. It is through the lock provided for them that the laborers enter and make their exit by means of a double door which allows of access to the cylinder, in which there is a small iron ladder that leads to the working chamber. The locks are lighted, and those for materials, which are provided with windlasses, have automatic doors. Access to them is had by means of lighters. The section of one of these caissons that we give in Fig. 1 very well shows the general plan.

The machinery of the working station, installed in the open air upon a terrace in the vicinity, produces, with 80 h. p., the compressed air necessary, as well as the electricity that supplies the ten incandescent lamps of each submerged working chamber. Two gangs of laborers continually replace one another in the caissons in order that the excavating and the laying of the masonry may never be interrupted, day or night.

Finally, when it becomes necessary to change the location of a caisson, lighters lashed together and provided with towing apparatus make fast to it and move it to its new position.

It will be seen that this is an important work that is to be accomplished in the port of Marseilles. According to the law of 1893, the total cost is estimated at twenty million francs, a third of which is furnished by the Chamber of Commerce, while the remainder will have to be provided for in the annual budgets of the Minister of Public Works. In order to assure the service of the loan that the contribution of the Chamber of Commerce has exacted, a toll of five centimes per ton is collected at the entrance upon merchandise coming by sea, as well as upon the heads of cattle.

It must not be supposed that the government shows a particular generosity toward the first port of France. In fact, from 1811 to 1892, while eighty-eight million francs were spent for Havre and forty-two for Dunkirk out of the funds of the treasury, only seventy-six millions have been appropriated for Marseilles. And yet the annual amount of custom duties collected at this port alone reaches nearly this figure. —La Nature.

THE COMPARATIVE ADVANTAGES AND DISADVANTAGES OF STEAM, COMPRESSED AIR AND ELECTRICITY FOR POWER PURPOSES IN COAL WORKING, WITH SPECIAL REFERENCE TO COAL CUTTING AND HAULAGE.

(The Iron and Coal Trades Review Prize Essay.)

By G. E. J. MCMURTRIE, A.M. Inst. C.E., Cinderford.

IN considering the comparative advantages and disadvantages of steam, compressed air and electricity for power purposes, with special reference to coal cutting and haulage, the writer is much struck by the careful manner in which the efficiency of most, if not all, recent important electric installations has been tested. The same remark may be applied to the more recent extensions of the use of compressed air at Paris and Birmingham; whether the efficiencies of the large air compressing plants still being put down at collieries, especially in South Wales, are noted with equal care, is probably open to question.

Mr. Nicholas Wood found, as the result of experiments, that, where no special source of loss existed, underground hauling engines can realize an efficient performance of 40 to 50 per cent. of the pressure of the steam upon the piston, and with the improved engines of the present day the value may be safely increased to 50 to 60 per cent. (estimated) in coal conveyed. Few recent records can be found of steam haulage plants, although doubtless many are still being put down.

The efficiency of such a plant is seldom recorded. If taken, the actual cost of haulage is given in cost per ton per mile, the principal costs being grouped under the heads of ropes or chains, maintaining plant, coal and labor. The first cost comprises that of wagon way, plant and original cost of boilers, engines, etc., the comparative first cost per mile of wagon way being thus obtained.

The writer would have expected that those in favor of the older systems of steam and compressed air haulage, in the face of the keen competition of electricity, would have gone to considerable trouble to put forward confuting figures; yet, when this question has been brought before mining institutes, general statements alone have been produced on their behalf, and exact figures, which have been almost ostentatiously displayed by the advocates of their powerful rival, have been withheld.

This has greatly added to the writer's difficulties, as, whatever may have been his predilections, actual records of hard facts can alone carry weight and be considered.

The principal purposes for which power will be required at collieries are winding, hauling, pumping and coal cutting, and hitherto steam alone has been

used in this country for the first purpose, although a large winding plant of 300 horse power has, the author understands, been dispatched to and erected at the De Beers mines in South Africa, and is in successful work.

Possibly, too, instances could be found of small installations in England for raising material from shallow staple pits.

But here the record of electric winding has ended, although able papers have been written advocating the entire use of electricity as the motive power of a colliery largely on account of the greater efficiency that would be obtained from one central plant, instead of, as now, a number of scattered plants, with steam supplied to them in a very wasteful manner, and the admittedly great convenience of electric cables for conveying the motive power to the motors. If this were done the central plant should consist of a number of smaller engines, just as with dynamos at a central lighting station, which could be put on or off as the load came on or off; otherwise, in the event of the central engine breaking down, everything would be at a standstill. Unless there were a duplicate plant, which would entail large additional capital expenditure, no one could ascend or descend the shaft till the breakage was repaired, and the stoppage of the fan would probably mean serious consequences.

While such a scheme would undoubtedly be economical in motive power, and probably in first cost, it can hardly be considered within the range of everyday practice.

As yet the winding engine, placed close to the boiler, is universally driven by steam, and in spite of the wasteful character which is due to the varying loads, and which necessitates at its maximum load (probably) four times the quantity of steam that its minimum load requires, i. e., when reaching top, it is likely to remain so, unless, as is probable, some such arrangement of electric motors be tried as that suggested. In that case, as the power required by fan, pump and haulage (supposing endless rope to be the system) is pretty regular, the extra power beyond the average required by the winding engine at its maximum can be got from a motor that can be thrown in when required and cut out as soon as done with. Thus used, no waste of power would take place, and there would be sufficient to lift the maximum load in place of steam being kept on the engine all the time, as is generally the case, except when the addition of the cutoff, regulated by automatic expansion gear, and arranged to come into work at a certain engine speed, has reduced this waste of power.

HAULAGE.

If we now consider the question of haulage, much will depend upon the position of the haulage plant and upon whether the colliery is a new or an old one. In the former case the haulage engine may (1) be put at the surface and main and tail or endless ropes taken down the up-cast pit; or (2) the haulage engine may be put down at the bottom of the down-cast pit and steam taken to it; or (3) in some cases both boilers and engines may be put underground, the boilers being fed with a split of fresh air and the hot gases utilized to assist the ventilation. The question of additional haulage plant would not be raised until the management was satisfied that the main haulage, which we will assume to be 2,000 yards in length, could not be extended further.

Let us first consider the case of the haulage required by a new colliery.

At once the question is raised of what motive power is to be adopted, the three possible powers being steam, compressed air and electricity. If the present haulage alone has to be considered and nothing thought of future extensions, the probable verdict will be to place the steam engine at the pit top and take driving ropes down the up-cast pit.

It must be apparent, so long as both the air compressor and the electric generator have to be driven by steam on the top, that a pair of horizontals of equal power driving a steam haulage, a compressed air haulage and an electric haulage, must yield a greater efficiency for steam haulage than either compressed air or electricity, as, whatever the losses may be in the steam engine, to these losses will have to be added, in the case of compressed air, the loss in compression, that in conveying the air down the pit in pipes to the motor and that in the motors. In the case of electricity there is to be added the loss in the generator, the cable and the motor. Against the steam haulage would have to be charged only the additional friction caused by taking the rope from the engine down the pit to the place where the electric motor or compressed air haulage engine would be placed. If we look at it from the point of view of first cost, we have to add the following to the cost of the engines, which is common to all three systems, viz.:

1. In the case of steam haulage, some 1,600 yards of rope, on the supposition that the shaft is 600 yards deep, and an endless rope is used, which would be a very small matter.

2. In the case of compressed air, the cost of the compressor and the air mains.

3. In the case of electricity, there would be the additional cost of the generator, cables and motor.

From this point of view the case in favor of steam haulage is still stronger.

If now the case of a steam haulage engine placed underground and close to the pit bottom is taken and compared with compressed air and electricity as before, we find the following: The efficiency and first cost of the compressed air and electrical haulage plant will remain the same. But in the case of steam haulage we have not only first to deduct the loss of efficiency due to the friction of the additional 1,600 yards of rope, but have to add the far more serious loss caused by the condensation and consequent loss of pressure in bringing the steam from the boilers to the haulage engine, a supposed distance of 800 yards.

The steam pipes would, no doubt, be well covered with non-conducting composition, which, the makers state, reduces the consumption of fuel by 15 to 30 per cent., due, doubtless, to the greatly reduced condensation in the covered pipes.

Mr. W. E. Garforth has stated that at the West Riding collieries steam is taken underground to a pair of 16 inch haulage engines, a distance of 526 yards, with a pressure of but 3 pounds to 4 pounds less than at the boilers.

He instances at the same colliery a pair of 15-inch engines, 187 yards from the boilers, supplied with steam from the top, with a loss of but 3 pounds in pressure and very little condensation.

Mr. H. W. Hughes, in his text book on mining, states that the loss from taking steam down the pit ranges from as little as 4 to 5 pounds to as much as 8 to 15 pounds.

At Broomhill colliery, Northumberland, steam is conveyed to a pump 1,414 yards from the boilers at bank. All pipes are well covered with non-conducting composition, and the loss by condensation is 21 per cent., while the pressure at the pump is 13 pounds below that at the bank.

Mr. Baure has stated that at the Bezinet colliery, France, steam is conveyed 400 yards from the boilers in 8¼-inch pipes with a loss of 18¼ per cent. Thus, apparently, at the very worst, a loss of 21 per cent. is got from condensation in well-covered pipes, while in other well authenticated cases the loss is but some 6 per cent.

This wide range must depend on whether the shafts and roads are wet or dry and whether the pipes are taken down the up-cast or down-cast pit. The additional first cost of this plant would be the cost of the steam pipes and fixing them, from which must be deducted the saving of 1,600 yards of rope.

Mr. W. Meacham has recently stated that the first cost of an electric haulage plant put down at Haden Hill colliery was nearly double the estimated cost of a similar steam haulage plant under the above conditions.

It is clear that the additional first cost of the compressor would be the compressor itself.

On the supposition that there is a loss of 20 per cent. of efficiency, the steam engine still must be the cheaper motive power, both in first cost and efficiency.

The third case, in which both boilers and engine are placed underground, will next be considered.

This must be the most unsatisfactory of the three methods of arranging for steam haulage close to the shaft.

In the case of fiery collieries, which form by far the larger number of the collieries of this country, few, if any, would dare attempt such a thing, and her Majesty's inspectors would be certain to do their best to prevent such a dangerous arrangement.

So far as these collieries are concerned, we may at once dismiss this arrangement, which, however, in non-fiery collieries may be considered feasible, but it has such great disadvantages as to be inadvisable. Allowing that a small Lancashire boiler be required to provide the necessary steam, a second would have to be provided for times when the one required repairs and had to be knocked off for the necessary cleaning.

This alone would entail a large capital expenditure, which would be further added to by the large cost of the necessary foundations and the arches that would have to be turned over the boilers.

The providing of suitable water, free from excess of lime and CO_2, is frequently an insuperable difficulty, and, if found, would require to be carefully collected and piped down the shaft to the boilers. The boilers would doubtless be placed in an intake, and should, if possible, have but a short return to the up-cast shaft, where the gases would be utilized for assisting or creating the ventilation, together with the exhaust steam, unless arrangements were made for the condensation of the latter by the engine itself, which would be feasible if the system of haulage be endless rope.

To keep this road, arching would be necessary throughout, which would be a further expense. The cost of repairs to the boiler would certainly be great, owing to probable heavy firing during the working day and the daily after-contraction consequent upon the dampers being put in.

Thus the first cost of boilers and haulage engine would in this case fully equal the first cost of either the electric or compressed air plant.

An increased efficiency would doubtless be secured, as the full boiler pressure should be obtained in the engines. An additional man would be required to look after the boiler, and a considerable part of the fuel used would be additional to what would have been used had steam been brought from the top, both of which must add to the working cost. Beyond this there is the constant danger of firing either carbonaceous matter in the surrounding strata, or more probably the seam of coal itself in which the plant would probably be placed, unless an air space has been left all round the boiler seating and arching and part at least of the boiler flue. Summing up, the advantage of an increased efficiency would, in the writer's opinion, be outweighed by the increased working cost and the much larger first cost, and this arrangement is considered by him inadvisable, even in a non-fiery colliery.

Mr. A. L. Steavenson, when comparing the three powers—steam, compressed air and electricity—came to the conclusion that, for distances of less than a mile, ropes driven by an engine placed at land were cheapest, and for distances of a mile to 2,000 yards wire ropes gave results equal to any system of transmission. In his paper he quoted Prof. Reynolds, who stated that ropes have been found without question the most efficient means of transmitting power at long distances.

Haulage driven by means of a separate endless shaft rope is certainly the best method of bringing the ropes from top, the slow speed at which such ropes travel almost preventing breakage, while yielding a long life. In case of breakage, too, the defect is soon remedied, while main and tail ropes are frequently taken down shafts where the roofs are not good enough to allow of the width of road necessary for endless rope haulage. The higher speed at which these ropes must run greatly adds to the risk of breakage. The writer has frequently been struck with the needlessly high speed at which many main and tail ropes are driven. It is a pretty and striking sight to see a train traveling fast, but the consequent wear and tear of the rolling stock, the road and the ropes should be considered, and a rate of speed forbidden beyond that which is absolutely necessary to comfortably meet the cage. If possible, to prevent delay in case of accident, the ropes should be taken down the up-cast or fan shaft, which shaft, it is presumed, will be used for ventilation only, for raising and lowering men and for putting down timber. The ropes, too, should be allowed to hang clear in the shaft, simply passing over pulleys at the top and bottom of the shaft. This, in case of a broken rope, will prevent delay, and also, in the writer's opinion, prevent the great loss of time that has occurred with main and tail ropes when the rope has sloughed, probably at the entrance to the wooden rope trunk. Should the system of hauling be main and tail, it would be well to stop the rope while men are raised and lowered in the shaft.

While in the writer's opinion there can be little doubt that haulage driven by steam on the top and haulage driven by steam taken down the pit is more efficient and cheaper in first cost than when either air or electricity is used, and that with boilers placed underground the efficiency is probably greater, the first cost is approximately the same, and the working cost the same as for either compressed air or electricity, yet when the time has come for the main haulages to be extended the conditions are quite altered.

We will suppose that the main haulage plane of a fiery mine is 2,000 yards long and has to be extended, say, a further 1,500 yards.

COMPRESSED AIR VERSUS ELECTRICITY.

Reliable data are now obtainable to decide the relative efficiency of compressed air and electricity. We will first consider compressed air. In an able paper read recently at the South Wales Mining Institute Prof. Elliott gave the following figures. On the ordinary simple adiabatic system of air compression, and neglecting certain losses, he found by calculation the efficiency of transmission, i. e., the ratio of the indicated horse power developed in the motor cylinder to the indicated horse power absorbed in the compressor cylinder to give in the case of a pressure of 90 pounds—which is the pressure at which the Popp installation of compressed air at Paris works—an efficiency of 59·5. But Prof. Kennedy found by actual measurement that he got for this efficiency but 46·1, and the difference represents the losses overlooked. Prof. Elliott also found that a compound system would have a possible efficiency of 77 per cent., and the triple system a possible efficiency of 84 per cent. On correcting his estimate in the ratio of 46·1 to 59·5, he got the probable actual efficiency of:

	Per cent.
Simple	46·1
Compound	59·8
Triple	65·2

If, however, we take this efficiency to be the ratio of the indicated horse power in motor cylinders to indicated horse power developed in the steam cylinder of the compressor, and making the same correction, we get:

	Per cent.
Simple	39·1
Compound	50·7
Triple	55·3

Allowing for losses on the scale found to exist by Prof. Kennedy in the Paris machinery, and reckoning from the steam cylinders to the motor cylinders, we get the following probable efficiency:

	Per cent.
Simple compressor and simple motor	39·1
Compound compressor and simple motor	44·9
Triple compressor and simple motor	46·9
Compound compressor and compound motor	50·7
Triple compressor and triple motor	55·3

Prof. Kennedy in the Paris experiments found the mechanical efficiency of the motor to be 0·67. This is somewhat low. If we take 80 as a good average value of the mechanical efficiency of the motors, we have for the efficiency of the several systems under the conditions assumed and reckoned from the steam cylinders of the compressors to the driving point of the motors the following results:

	Per cent.
Simple compressor and simple motor	31·28
Compound compressor and simple motor	35·92
Triple compressor and simple motor	37·52
Compound compressor and compound motor	40·56
Triple compressor and triple motor	44·24

Take an installation working on the simple adiabatic plan at the reservoir pressure of six atmospheres absolute, the saving of indicated horse power in the steam cylinders of the compressor which would be effected on replacing the old by each of the new systems would be found by calculation to be:

	Per cent. saving.
Compound compressor and simple motor	12·9
Triple compressor and simple motor	16·7
Compound compressor and compound motor	22·9
Triple compressor and triple motor	29·3

These figures show that with the ordinary simple compressor but 31·28 per cent. of efficiency is got, which in general practice probably would drop to 20 per cent., or at most 25 per cent., and if a compound compressor and a simple motor be used, as have been adopted for several large air compressing plants now being put down in South Wales, an additional 4⅔ per cent. is got. If both compressor and motor are compounded, as has been done at the Newbattle collieries, an additional 9¼ per cent. is obtained.

These figures are not encouraging, and it may be questioned whether the additional efficiency obtained from compounding the compressor, or both compressor and motor, will authorize the additional capital expenditure necessitated by the additional plant.

Practically, with the same pressure of transmission we can obtain this increased efficiency; or with the same efficiency we can obtain a reduction in the size of the supply pipes and plant if we adopt a higher initial pressure, which probably would be found the better plan financially. The following are some of the practical difficulties which cause this low efficiency and the suggested and practical remedies.

The isothermal system of compression having been found unattainable in practice, adiabatic compression alone has to be considered.

(To be continued.)

One hundred miles of the Uganda Railroad have been completed and will be thrown open to traffic at once. There remain 300 miles to be constructed before the Victoria Nyanza is reached. The last 40 miles were laid down in a little over two months.

ELECTRICAL NOTES.

According to the English journals the declaration of "Officier de l'Ordre Léopold" has just been conferred upon Prof. D. E. Hughes, of London, by the King of Belgium, says The Electrical World. The Hughes type printing telegraph has been used largely on the Belgian government lines for over twenty-seven years.

At the end of October, 1896, there were in use in Paris 545,914 electric lamps and in London 1,178,000, according to Zeitschrift für Architectur. The feeding current was in Paris 8,107,353 kilowatt hours and in London 10,000,000 kilowatt hours, approximately. In Paris the price per kilowatt hour was 1·25 franc and in London 0·65 franc.

The Baltimore and Ohio Southwestern Railway has been trying electric motors on turntables, says Locomotive Engineering. It cost an average of less than one-half a cent for each time the table was turned. When the same table was operated by hand, it cost twelve cents for each engine. The yearly saving is said to be about $700.

We believe it is a general stipulation in American tramway specifications that the trolley wire should stand a breaking strain of 30 tons per square inch. To some extent consulting engineers in this country, says the English Electrical Review, are insisting upon a similar strength; but it is questionable, not only whether 30 tons is necessary, but whether that figure is ever obtained in ordinary practice. From some recent tests carried out on both English and American trolley wires, it would appear that the average test is about 23 tons per square inch, as will be seen from the following:

ENGLISH WIRE.		Tons per square inch.
Sample A	No. 0	25·4
Sample B	No. 0	23·9
Sample C	No. 0	23·9
Sample D	No. 0	24·07
AMERICAN WIRE.		
Sample A	No. 0	20·2
Sample B	No. 0	23·4
Sample C	No. 0000	21·1

It would, at any rate, appear that some of the American wire sent to this country is a long way short of 30 tons per square inch, though it would no doubt withstand all the strains that are likely to be put upon it in practice.

The Pennsylvania Railroad Company has decided to lend its aid in the work of solving the problems, also doing this in co-operation with the mechanical engineers and scientists and men of financial authority who are associated with George Westinghouse. The Pennsylvania company has already laid a track for the purpose of making these experiments which offers five miles of trackage, and is placed in a singularly convenient region for the accurate testing of various plans and inventions, the swift remedy of defects and the careful study of every appliance which any person may offer for inspection or test. The tracks, says The Philadelphia Press, have been laid down in East Pittsburg, almost parallel with the Pennsylvania Railroad tracks, although in the valley beneath those tracks, in which the Westinghouse works are situated. Already in those vast yards a system of electric propulsion has been in use for several years. By it the freight cars, which are switched into the yard and which carry from the works the machines destined for distant markets, have been hauled with economy, perfect ease and method. It is what is known as the button system. The third-rail system is also to be tested in every detail. The tracks which the Pennsylvania Railroad has established, and which the Westinghouse people are utilizing with an electric car, are supplemented by two interior rails. That is to say, it is not a single third rail system, but is what may be called the double third-rail system. This system is now being tested upon these tracks, very largely for the purpose of determining whether the element of danger can be completely eliminated, and, if this can be done, whether the system thus established can be operated as economically and as satisfactorily in other ways as the third-rail system with the live rail, such as President Clark is using upon the branch line near Hartford, Conn.

A dispatch has been received at the Foreign Office from the British minister at Belgrade, on the subject of a contract between Mr. Hugo Luther, of Brunswick, and the Servian government, which has passed the Shupshina, and has been promulgated as a law in the Servian Official Gazette. The rights conferred on Mr. Luther by this instrument are of a remarkable and extensive nature, says The Electrical Review. He will enjoy for 99 years the exclusive privilege of drawing mechanical and electrical power from the cataracts on the Servian shore of the Danube, and of applying same to any industrial undertaking on which he may decide to embark. During the first 30 years of this period his plant, buildings and industrial undertaking are exempted from the payment of every description of impost, taxes, octroi or custom dues on the importation and exportation of machinery, material and produce. Within four years from the date of the contract, Mr. Luther must erect motor plant and buildings at the cataracts to the value of 2,000,000 dinars, and electric power for working purposes must be available within a period of eight years, failing which, he forfeits all his rights under the contract, with the exception of those over mines. Within 30 years electricity to the amount of 15,000 horse power must be forthcoming, and every cataract then unused by Mr. Luther reverts to the state, which may allot them to other parties after Mr. Luther has been given the option of using them. At the end of 99 years the state may exercise a right of pre-emption over the power-producing plant and buildings. All matters of dispute between the state and the concessionaire are to be adjusted by a court of arbitration to be specially appointed, whose members will be chosen in equal proportion by the government and by Mr. Luther. This measure places mineral forest resources of nearly 600 square miles of the northeastern portion of Servia under the control of foreign capitalists. The capital required by Mr. Luther will probably be shortly raised in Germany.

MISCELLANEOUS NOTES.

A diamond in constant use for cutting cold glass lasts about three months, but if, used to cut hot glass, it would only last for one day.

Sumatra petroleum promises to be a rival of Russian and American oils in Japan. A Yokohama firm has ordered 40,000 cases of the Sumatra oil. The packing cases are to be made of American lumber.

The general annual return of the British army for 1896 shows an average effective strength of 220,742, subdivided thus: Household Cavalry, 1,300; Cavalry of the Line, 16,284; Horse Artillery, 3,785; Field Artillery, 14,451; Mountain Batteries, 1,408; Garrison Artillery, 17,663; Royal Engineers, 7,833; Foot Guards, 5,850; Infantry of the Line, 137,022; Colonial Corps, 3,218; Army Service Corps, 2,517; Ordnance Corps, 1,310; Medical Staff Corps, 2,682; and Army Pay Corps, 569. 76,937 of all ranks were quartered in England, Wales and the Channel Islands, 3,650 in Scotland, and 25,841 in Ireland (being an average at home of 106,408), 38,864 in the Colonies and Egypt, and 75,450 in India. The net loss from desertion was in the downward direction, namely, 3,307, as against 3,453 in 1895, and 5,423 in 1886. In addition there are 78,182 Reservists, 117,778 Militia, 30,374 Militia Reserve, 10,362 Yeoman Cavalry, 220,034 Volunteers.—Army and Navy Journal.

Certainly there is nothing more uninteresting to the metallurgist, says The Engineering and Mining Journal, unless it be an essay in pure mathematics, than an account of the redetermination of the atomic weight of a certain element. The question is often asked, Why are new determinations important? Are not those now accepted good enough for practical purposes? To this question Mr. F. W. Clarke makes the following answer: There are two rival values for the atomic weight of chromium. The 52·5 based on the old work of Berlin is still used by European analysts; the other, 52·1, based on later and more accurate researches, is used in the United States. The Baltimore chrome ore works import chromic iron in cargoes of about 2,300 tons, which are assayed in Glasgow and Baltimore. The chemists of the former city based their percentage calculation on the atomic weight of chromium, 52·5, and those of the latter place on 52·1. The variation in percentage resulting from this amounts to a difference of $367.50 in the value of a cargo.'

It is not uncommon for noblemen with picture or sculpture galleries 100 feet long to find a difficulty in keeping their servants. Lord Londonderry has a gigantic house in Wynyard Park, Durham, 300 feet long, which is bad enough; but the sculpture gallery, which is 101 feet long by 58 feet high, contains no less than 700 pieces of statuary and 300 paintings. This gallery has to be swept out and dusted every day. Suffice it to say that Lord Leconfield is the owner of Petworth House, a truly wonderful building, 322 feet long, and containing over 100 rooms, many of them of vast proportions. The Duke of Richmond's house at Goodwood, with its two wings, measures 378 feet, and gives employment to over sixty domestics. There are 125 rooms in Castle Howard, the Earl of Carlisle's residence near Maldon, Yorks. When it was refurnished some years ago, forty suites of new furniture were required. We will conclude with a brief reference to Eaton Hall, Cheshire, the seat of the Duke of Westminster. The writer well remembers, when going over this house, being taken to a corridor which runs the whole breadth of the building. "How far is it to the other end?" I asked. "Four hundred and seventy-two feet," was the reply.—Illustrated Carpenter and Builder.

A new ticket printing machine now being introduced to the notice of the English railway companies is designed to simplify the work of the ticket issuing department and to facilitate audit, says The Colliery Guardian. This new machine is intended to supersede a central ticket printing office altogether, and to enable the booking clerk to print each ticket as it is asked for by the passenger. At one side of the machine there is a wheel on the circumference of which are engraved the names of the various stations. This is turned round until the name of the station for which a ticket is desired comes opposite the pointer. In front are several levers; when one of these is touched, according to the class required, a printed ticket is forthwith delivered bearing the names of the stations from which and to which it is available, the class, the fare, the date, the serial number, and any other particulars that may be wanted. If the pressure on the lever is continued, tickets printed in this way, and all serially numbered, may be poured out at the rate of one hundred a minute. At the same time the number, distinction and price of each ticket issued are automatically registered on continuous rolls of paper, one for each class, which are locked up within the machine and can only be reached by the official to whom the key is intrusted.

Japan has shown herself so remarkably go ahead in recent years that we read now without much surprise of the strides made by her chief ports and cities, says The London Financial News. Hakodate is no exception to the general rule, and our consul there, in his report on its trade during 1896, gives some striking figures. The total foreign trade of the port last year amounted in value to £132,689, an increase of £34,860 on the total in 1895, or at the rate of nearly 35 per cent. The exports rose from £81,075 to £97,300, while the imports more than doubled, leaping from £16,704 to £35,279. This was partly due to the importation of railway material. In the table of exports those to China stand first with a total of £37,329, against £45,873 in 1895; but in the import table the flowery land is last but one, with the insignificant total of £139, against £181 in the previous year. Exports to the United States come next—£22,283—a falling off of 1895's figures of about £3,000; while the imports thence stand lowest with £75 only for 1896, against £218 for 1895. Exports to Russian Asia rose to £10,963 from £2,471 in the preceding year; and the imports thence sprang from £5,007 in 1895 to £16,650. Great Britain, which stands fourth in Hakodate's list of exports, is an easy first in the list of imports, the figures being £18,149, against £11,124 in 1895. This, although not such a relatively large increase as the imports from Russian Asia, shows that our commercial intercourse with this rising Japanese port is being well sustained.

SELECTED FORMULÆ.

Poultry Food.—There is a great similarity between the various poultry powders and foods. The powders are popularly supposed to increase the egg-laying power of hens. We quote a few typical formulas:

Powdered eggshell or phosphate of lime	4	ounces.
Iron sulphate	4	"
Powdered capsicum	4	"
Powdered fenugreek	2	"
Powdered black pepper	1	"
Silver sand	2	"
Powdered lentils	6	"

A tablespoonful to be mixed with sufficient feed for twenty hens.

Oyster shell, ground	5	ounces.
Magnesia	1	"
Calcium carbonate	3	"
Bone, ground	1½	"
Mustard bran	1½	"
Capsicum	1	"
Sodium chloride	1	"
Iron sulphate	½	"
Sodium carbonate	½	"
Sulphur	½	"
Beef, lean, dried and powdered	10	"
Fine sand	10	"
Corn meal	20	"
Linseed meal	20	"

Reduce all to moderately coarse powder and mix well.

The above are formulas that are recommended by poultrymen, and pharmacists should not condemn them, even if they do seem polypharmic. Poultrymen have ideas of their own about the value of complicated formulæ.—American Druggist.

Luminous Calcium Sulphide.—Calcium sulphide as used in the manufacture of luminous paint may be prepared upon the small scale by the following process: Boil for one hour 2¼ ounces of caustic lime, recently prepared by calcining clean white shells at a strong red heat, with 1 ounce sulphur and 1 quart soft water. Set aside in a covered vessel for a few days; then pour off the liquid, collect the clear orange colored crystals which have deposited, and let them drain and dry on bibulous paper. Place the dried sulphide in a clean graphite crucible provided with a cover. Heat for one-half hour at a temperature just short of redness, then quickly for about fifteen minutes at a white heat. Remove cover and pack in clay until perfectly cold. A small quantity of pure calcium fluoride is added to the sulphide before heating it. It may be mixed with alcoholic copal varnish. Sulphides of barium and strontium also give phosphorescent powders when duly heated. Each sulphide has a predominant color, but the temperature to which it is heated has a modifying effect on the color. Calcine in a covered crucible, along with powdered charcoal, sulphate of lime, sulphate of barytes, or sulphate of strontia; there is produced in each case a grayish white powder, which, after exposure to strong light (either sunlight or magnesium light), will be phosphorescent, the color depending on the sulphate used and the degree of heat employed.—Pharmaceutical Era.

To Color Iron Blue.—One hundred and forty grammes of hyposulphite of soda are dissolved in a liter of water (4½ ounces to 1 quart); 35 grammes of acetate of lead are dissolved in another liter (1¼ ounces to 1 quart); the two solutions are mixed, are made to boil, and the iron is immersed therein. The metal takes a blue color, such as is obtained by heating it.

Receipt for Ink to Write on Glass.—

Water	500	parts.
Borax	75	"
Alcohol	300	"
Fish glue	40	"
Methyl violet	3	"

By volume. The ink is indelible, and very easily applied to the surface of the glass.—Cosmos.

To glue celluloid to wood, leather, etc., use a mixture of 1 part of shellac, 1 part of camphorated spirits, and 3 or 4 parts of 90 per cent. alcohol. A collodion solution may also be used, or an alcoholic solution of fine celluloid shavings.—Uhland's Wochenschrift.

To color ivory brown, apply several coats of an ammoniacal solution of potassium permanganate. Similar results are obtained if the solution is diluted with vinegar, and the ivory article allowed to remain in the liquid for some time.—Uhland's Wochenschrift.

To whiten old ivory, wipe it with flannel which has been wetted with essence of turpentine, then expose for several days to the sun.—La Vie Scientifique.

A Solder for Aluminum.—As an important article in mechanical construction, aluminum is slowly but surely finding a place for itself, but one obstacle to its more general introduction has been the difficulty experienced by manufacturers to find a solder that will successfully effect a juncture between parts. The Journal of the Franklin Institute now gives a recipe for a solder which is said to serve the purpose. It is called Green's solder, and is composed of zinc 50·03 per cent., tin 47·99, aluminum 1·76, and phosphorus 0·22 per cent. It is not used with any flux, simply requiring the aluminum faces to be cleaned and first coated with the solder, then with a clean hot soldering bit to wipe the soldered joint to be made. This may be a very good solder, but if such extreme accuracy as the decimals imply is really necessary in apportioning the ingredients, we fear it will operate against its general use.

Adhesion of Cork to Metal.—In fastening cork to iron and brass, even when these are lacquered, a good sealing wax containing shellac will be found to serve the purpose nicely. Wax prepared with resin is not suitable. The cork surface is painted with the melted sealing wax. The surface of the metal is heated with a spirit flame entirely free from soot, until the sealing wax melts when pressed upon the metallic surface. The wax is held in the flame until it burns, and it is then applied to the hot surface of the metal. The cork surface painted with sealing wax is now held in the flame, and as soon as the wax begins to melt, the cork is pressed firmly on the metallic surface bearing the wax.—Pharm. Centralhalle.

SCENES AROUND PNOM-PENH, THE CAPITAL OF CAMBODIA.

ONE of our correspondents in Pnom-Penh sends us a few interesting photographs of this region, which but very recently was causing itself to be talked about. It was a question of nothing less than a coup d'etat, as a sequel to which King Norodom was dispossessed of his throne under the pretext that he had given signs of mental alienation.

In the train of these events, the resident general was changed, and replaced by M. Ducos, whose merits have caused him to be highly appreciated in these quarters.

This region is of uneven aspect, with a central canal of which the emanations are unwholesome to such a degree as to cause cholera when the water gets low. The landscape is picturesque; and picturesque, too, are those returns from hunting that unite numerous sportsmen around the game that has been killed during the day. Wonderful accounts are given of these hunting expeditions, in which there usually occurs a surprising slaughter of pea fowl, deer, and wild boars, the number of which would make our European Nimrods pale with envy. But, doubtless, more original still is this imposing line of elephants massed in an alley of the garden of the official French residence, and upon which are seated the guests invited to an excursion organized by Mme. Ducos. One thinks involuntarily of Hamilcar's elephants in the narratives of the battle of Salammbo.

As a background to the picture, we see curiously and capriciously profiled the pyramidal towers of the pagoda of Pnom-Penh, one of the most celebrated edifices of the country. This pagoda, it is said, was erected through the piety of Lady Penh, a Cambodian of ancient times.

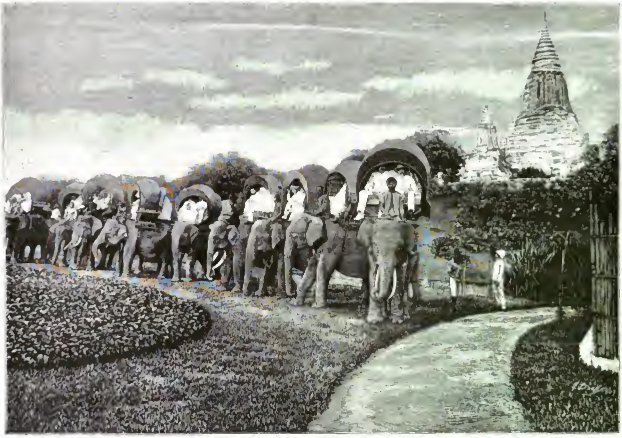
The capital of Cambodia, moreover, borrowed its name from the hill upon which this edifice stands. The name is from pnom, "mountain," and penh, "great abundance."

The hill was made by the hand of man, and the pyramid was erected over the place of sepulture of him who had it constructed, some eight hundred years ago, that is to say, along about the year 1080 of the Christian era, or in 1600 of the Buddhic era of Cakia-Mouni, the golden age of Khmer architecture.

If tradition is to be believed, the Khmers were one of the first barbarous tribes that occupied Cambodia. Aside from the structures that are attributed to their art, and of which the pagoda of Pnom-Penh and the celebrated ruins of Ang Kor give the best idea, scarcely anything exists relating to them except legends. The latter speak of a certain Bautumo Saurivong, whose name in Hindoo signifies "the lotus, son of the sun," and to whom the pagoda of Ang Kor is attributed. The present Cambodians consider themselves as the descendants of these Khmers.

Pnom-Penh is situated upon the left bank of the Mekong, near the confluence of the arm of the lake, at 138 miles from Saigon and 84 miles to the north of the Gulf of Siam.

The city is built upon a marvelous site. It is the residence of the king, of the resident general of France, and of the resident of the province. Although the smallest of the Kingdom, this city is the richest and most densely populated. It contains 340,000 inhabitants. Besides the pagoda spoken of above, there are here several other prominent edifices, the principal of which are the king's palace, the habitation of the chief of the bonzes, and the elegant buildings of the French protectorate, opposite which there is a large pleasure garden, the flower beds of which adorn the shores of the Mekong.—*Le Monde Illustré.*



AN EXCURSION ON ELEPHANT BACK AT PNOM-PENH, CAMBODIA.

THE MUSÉE SOCIAL AND ITS WORK IN SWITZERLAND.*

THE Musée Social of Paris, France, is a privately endowed but public institution, the object of which is to advance the study of practical labor questions throughout the world. Though in no way a state institution, it may be said to be a labor bureau the maintenance of which is provided for by funds with which it has been privately endowed. Under these circumstances its organization and work merit a special interest. The Musée was created in 1894 by the Comte de Chambrun, who gave for that purpose the sum of 1,700,000 francs ($328,100), but it was not definitely organized and inaugurated until March 25, 1895. Its objects, in the language of the constitution, are "to place gratuitously at the disposition of the public documents with collateral information, models, plans, constitutions, etc., of social institutions and organizations which have for their object and result the amelioration of the material and moral situation of the laboring classes."

Unlike the various economic associations and societies, it as far as possible avoids mere academic discussions, and confines its attention to matter relating to practical labor questions. In this it follows strictly the line of work of official labor bureaus. In a building owned by it, it has accumulated a library of all the principal official reports, publications of private associations and industrial organizations, and private treatises printed in all languages bearing upon practical labor problems. It has fitted up rooms for lectures and meetings and for students who desire to make use of the library. It has a permanent exhibition of models, plans, etc., of workingmen's houses, devices for preventing accidents, constitutions of social institutions of all kinds, etc. It provides for lecture courses on labor problems.

As regards its own direct contributions to a knowledge of labor conditions, it from time to time organizes special commissions in France and in foreign countries to inquire into labor subjects of present practical importance. The publications of the Musée Social naturally constitute a very important part of its work. Of these there are several kinds. It issues from time to time volumes in a series entitled Bibliothèque du Musée Social, which give the results of its investigations and other material representing the results of original research. The second class of publications consists of more frequent bulletins, or circulaires, as they are called, for the publication of shorter contributions. There are two series of these bulletins, the first of which is intended for a wide gratuitous circulation among the working classes and is devoted to giving information concerning current happenings relating to labor, such as the meetings of labor congresses or organizations, social legislation, etc. The second series embraces studies more in the nature of economic monographs. A most important feature of these bulletins is the valuable bibliography of reports and works relating to the question under treatment, which is always appended.

The bulletins relating to the insurance of workingmen against idleness in Switzerland are of such general interest that their contents are here summarized. Switzerland is apparently the only country in which serious efforts have been made to lessen the evils of lack of employment through the creation of special state insurance institutions. The first attempt to provide for insurance against idleness under government auspices was made by the town of Bern, in April, 1893. It provided for the creation of an institution, membership in which was to be purely voluntary. Each member was required to pay monthly dues of 40 centimes ($0·077). To the fund thus accumulated the town agreed to add a subsidy the maximum amount of which was limited to 5,000 francs ($965) a year. The constitution also provided for the receipt of gifts from employers and other individuals. This relief would be granted only during the months of December, January and February.

Only members of six months' standing who had paid their dues regularly and had been unemployed at least fifteen days are entitled to benefits, and then not for the first week that they are without work. A workingman who refuses work of any kind loses all right to aid of any kind. There are also other cases in which the workingman loses his right to a benefit. Such, for instance, are the cases where he is unemployed as the result of his own fault, and especially when he has engaged in a strike. The fund is administered by a commission of seven members, of which three are named by the municipal authorities, two by the employers contributing to the fund, and two by the workingmen.

This institution has now been in existence a sufficient length of time to furnish some indication of the character of the results. The members have contributed but 14 per cent. of the total receipts and they have received in actual benefits six times the amount paid in by them as dues. One would think that under such exceptionally favorable circumstances membership would increase rapidly. Such, however, has not been the case. During the second year, 1894-95, there were but 390 members, or 14 less than the preceding year. Two hundred and nineteen persons, or more than half the members, were aided. They received $1,890.06, or an average of $8.58 each. This institution had been founded for but two years as an experiment. In 1895, the two years having elapsed, the town council determined by an almost unanimous vote to continue it in operation. Some modifications, however, were introduced in its organization, and the municipal employment bureau, which had until then been an independent service, was attached to the work of the insurance fund.

Saint Gall, a town of about 30,000 inhabitants, was the first to follow the example of Bern and provide for the insurance of workingmen against idleness. Its policy, however, differed radically from that of Bern, in that it adopted the policy of compulsory insurance. Its institution was created June 23, 1895. After an existence of about a year and a half, its suppression, after June 30, 1897, was voted by a majority of the electors of the town November 8, 1896. The reasons for its abolishment were that the system of compulsion worked badly. At Basel, although no scheme of insurance has as yet been put into operation, a proposition for the compulsory insurance of workingmen

* Bulletin of the Department of Labor, Washington, D. C., March.—Public Opinion.

against lack of employment through a municipal institution has been elaborated, in which the attempt has been made to meet the objections that were urged against the Saint Gall experiment. The question of insurance against lack of employment has also received attention in other Swiss cities, notably Zurich and Lucerne, but no actual steps in this direction have as yet been taken. The federal government is now prosecuting an investigation of the whole subject of lack of employment and the means of preventing or lessening the evils resulting from it. The complete report of this investigation has not yet been made.

ALFRED KÖCHER AND HIS PACE MAKERS.

WE publish herewith an engraving of Alfred Köcher and his pace makers. For this picture, which was taken from an instantaneous photograph, we are indebted to our worthy contemporary the Illustrirte Zeitung. At the races which were arranged in the Friedenau-Wilmersdorf Park, near Berlin, for the benefit of the sufferers from the flood, Köcher succeeded in making 1·8 miles in 3 minutes 31⅘ seconds, thus beating the 3 minutes 32 seconds record of Joseph Fischer, which had formerly led the world. Köcher also made the road run of 62 miles in six minutes less than it had been made before, covering the distance from Zossen to Lübben and back in 2 hours, 51 minutes and 53¼ seconds.

ALFRED KÖCHER AND HIS PACE MAKERS.

THINGS AMERICAN.

By MARCUS BENJAMIN, Ph.D.

IT is a curious peculiarity of most people that they desire to obtain some reminders of places that they have visited. In a way, the habit is a good one, but, unfortunately, it is apt to degenerate into vandalism, and a piece of a curtain from the Palace of Sans Souci or a button from a Napoleonic uniform, obtained at the price of a generous douceur to the guide, is too frequently the kind of souvenir that the traveler brings back from abroad with him. On the other hand, a carved piece of bogwood from Ireland, a bit of porcelain from Sevres, a mosaic from Florence, a sash from Rome or a piece of glass from Venice, a miniature wooden chalet from Switzerland, an agate from Oberstein, or something in iron from Berlin, are indeed pleasant reminders of a visit to the old world.

It has often seemed strange to me that Americans, who travel so much about their own country, should have so completely ignored those things that are peculiar to the many places within our own land; and yet there is scarcely an important city in the United States that has not some one thing that is made nowhere else. Some of these deserve special mention, and as an interest, largely fostered by our sons, daughters and dames of patriotic societies, has been developed in "Things American," it seems well to describe some of the "things" that I have gathered.

At first blush it would appear as if in so great a city as New York, where everything can be had, no matter from where it originally came, no special memento, peculiar to the metropolis itself, was procurable, and yet there is nothing so artistic, so beautiful and so unique among the products of American industries as the Favrile glass, which Mr. Louis C. Tiffany has recently invented. It is made into a variety of original forms in vases and other objects of interest to collectors and lovers of art.

The new combinations of color with color, of color over color, the deepening of tone, the subtile quality of the texture, the introduction of new colors, the union of metal with glass, and the wonderful ornamental effects obtained by embedding lines and threads of one colored glass into that of another while they are in a molten state and during the operation of blowing, are among the characteristics of this beautiful invention.

As we journey from New York toward the South, Trenton is reached, and the collector of things beautiful would, indeed, find it a difficult task to get away from the sample rooms of the potteries of that city. Perhaps, if he goes to the right place, he may find some bit of modern historical ware, such as the exquisite pieces of Belleek, that were made for the World's Fair, held in Chicago; or a piece of the china set, with the heads of George and Martha Washington, that were made in 1876. There is also an interesting after-dinner cup and saucer, that I recall having seen, that was made for the New Orleans Exposition, in 1881.

Philadelphia is large, and while there may be things that are more characteristic, I have contented myself with the quaint toby jug, in old Rockingham ware, made there, and the two English plates, made in 1876, with prints of Independence Hall and the public buildings on them. The Mint affords one an opportunity of securing a specimen set of the silver coins or, perhaps, one of the medals made there, certain of which are exceedingly beautiful.

As we go west from Philadelphia, Gettysburg—famous as the field of the greatest of modern battles—may be taken in on the way. Bullets, pieces of shell, bayonets and the like are still common and far too plentiful to be other than genuine. It was less than ten years after the battle when I first visited the field, and then, among the "relics," that which most attracted my attention was a lamp, the bowl of which was made from an unexploded shell that had been carefully emptied of its dangerous contents.

At Summit Hill, in Carbon County, Penn., are to be had what are called "anthracite coal novelties." These are simply carvings in the hard coal, which takes a polish similar to jet; and they are quite attractive, especially when care has been taken to secure a specimen containing a vein of pyrite.

The largest aluminum works in the world are, probably, those near Pittsburg, and a pleasant souvenir of a visit to that city, so noted for its metallurgical works, is a plaque of the coming metal. A medallion, with the head of Woehler, who discovered the element, modeled in high relief, brings to mind some bitter cold days spent there several winters ago.

Baltimore is the home of the Chesapeake Pottery, and a specimen from its kilns—perhaps a cracker jar—in the Severn or Calvert pattern, is something that cannot be found in every city; while the "Rebekah at the Well" teapot, that originated in a pottery nearer the center of the city, is still procurable, but certainly not in the bric-a-brac shops, for there they prefer to sell, at fancy prices, English cups and saucers, decorated with views of the city.

The rare old blue plates with which the Baltimore and Ohio Railway celebrated its completion in 1828 will sometimes reward the antiquarian who is willing to spend time and money to secure one of these treasures, on which is printed the little, stumpy locomotive that was built by Peter Cooper, early in the century.

It is in Washington that we find something, perhaps, more unique than elsewhere. No visitor to the capital city of the Union can have failed to have observed the various souvenirs, made of a plastic material and in many shapes, and having a grayish color, that are everywhere for sale. They are of paper pulp, obtained from the government bank notes that have been reduced and macerated at the Treasury Department. The operation is an interesting one to see. Each object bears a small label giving the estimated value of the original bills, and one may easily bring away with him a souvenir with an estimated original value of $50,000. Less unique, but at one time quite common, were bits or chips of stone from the Washington Monument. On many of these were crude paintings of the tall white shaft, or else of some public building in Washington. At Mount Vernon canes and other commonplace objects in wood, grown on the place, are for sale, but they are without special interest.

The battle fields of Virginia afford relics, and a company in Richmond, Virginia, advertise a tastefully finished cane, ornamented with a silver plate, upon which is inscribed the name of the battle field from which it came, cut from any one of the following historical fields of the late war: Seven Pines, Fair Oaks, Gaines' Mills, Garnet Farm, Malvern Hill, Cold Harbor, or Petersburg.

The deposits of phosphate rock in South Carolina yield fossil sharks' teeth that form convenient paper weights, which are common in Charleston, where also the brilliant plumage of semi-tropical birds may be purchased, and with which fans are easily made. In Florida, especially in Jacksonville and St. Augustine, there are stores where paper cutters and other objects, carved from orange wood, are to be had. Stuffed alli

gators, so small as to be easily packed in a glove box, are everywhere sold. Fans in bright colors, like those from Cuba and Spain, with views of St. Augustine, from the old San Marco to the modern Ponce, are equally common. Shells and strange seeds, made into jewelry, abound; while pieces of the curious coquina stone, cut in squares or bricks, are sold for a few cents. It is with this material that many of the newer and beautiful buildings in St. Augustine are built.

It is in New Orleans that the curious carving wares from Mexico begin to appear. Here we find the strange pottery from Guadalajara, and the wax figures that the nimble fingers of the native artists fashion with such ease. Many of these are made in New Orleans itself. Nor must the feather work be forgotten, for it is not uncommon. But that which I value most from New Orleans are the Indian Choctaw baskets, that are still to be had in the French market. If the makers of them are as old as the saleswomen, surely, in years to come, they will be rarities of the first water, commanding high prices. Miniature cotton bales, that purport to have been made during slave times, are not without interest, and may be found in shops in Canal Street.

Before leaving the Southern States, it is well to remember that specimens of Confederate postage stamps and Confederate bills are on sale in many of the cities below Mason and Dixon's line.

If we ascend the Mississippi to St. Louis, we may be fortunate in finding some authentic piece of pottery from the mounds near that city. The vicinity is rich in the remains of that prehistoric people about whom so little is known. Indeed, St. Louis itself is on the site of several mounds. Magnificent quartz crystals are to be had for next to nothing at the Hot Springs, in Arkansas. Specimens that exceed in beauty the famous crystals from Switzerland are on sale along the principal street of the resort.

In Texas, steer horns, fully as beautiful as those from the cattle in the vicinity of Rome, Italy, are often to be found, and may be had for the asking. In San Antonio, with its never to be forgotten Alamo, and its beautiful missions that are slowly but surely crumbling into ruins, the products from over the line are sold to the curiosity hunters. Monkey jars and water bottles, feather work and carved onyx are seen in the shop windows.

Turning abruptly north, we find in Denver curiosities that are of Indian origin; but to my mind, the sprouting silver buttons that resemble an open rose are most interesting, while the large green garnets from Salida, that occur in perfect crystals, are souvenirs of greater local interest. Santa Fé is par excellence the place to purchase Indian pottery. Jake Gold's museum is known the world over, and in it may be had genuine specimens from most, if not all, the New Mexican Indian handicrafts. The Navaho blankets, that are so highly prized, are to be had here, while the more brilliant Mexican blankets, made in Santa Fé itself, are sold for far less than elsewhere. The smaller blankets, that cost from $3 to $4 in Santa Fé, readily command $10 to $15 on the Pacific coast. Indian baskets, from the coarse yucca to the more closely woven ones, are to be had, while silver ornaments, made by the Indians, will sometimes reward those who know what to ask for; and the still rarer paintings, on elk skins, are occasionally to be had. Gems, including agates and the turquoise from the Los Cerillos mines, near by, are sold in Santa Fé at reasonable prices, while on the south side of the Plaza are silversmiths, who make the curious filigree silver work that recalls a similar art practiced in Florence and elsewhere in Northern Italy.

From Santa Fé westward along the lines of either Atlantic and Pacific or the Southern Pacific Railways, Indian curiosities are procurable at all the larger towns. The large black ollas from Santa Clara, New Mexico, make handsome ornaments, and certainly much of the grotesque pottery of the Pueblo Indians is worth buying. At El Paso there are Mexican curiosities to be had, and especially if one is willing to cross the river into old Mexico by the only international horse car line in the world he will find large stores where Mexican opals that seem almost to have borrowed their brilliancy from the sun are common, while the rag, wax and feather work are lavishly displayed. Carvings of the so-called Mexican onyx, mostly of fruits, may be bought at reasonable prices, and one firm offers a ninety page catalogue with over one hundred illustrations for ten cents.

Near Fort Yuma, where the train enters California, there is an Indian reservation, and at the railway station the haughty braves who disdain to offer their wares are not loath to part with them for a few dimes. At Los Angeles, Mexican and Indian curios have well nigh disappeared, although here and there old California baskets are to be had, but they command a good price. Orangewood comes again into notice, and slabs of it in all sizes, from a few inches up to a foot or more, are to be had with attractive paintings of either the leaf, blossom and fruit of the tree itself or with the more somber representations of one of the old mission churches that are in the immediate vicinity.

Naturally there are curiosity shops at the delightful seaside resort of Coronado Beach, opposite San Diego. A small herd of ostriches are kept there on exhibition to show the development of a new American industry. An egg, emptied of its contents, or one of the plumes can readily be purchased. Polished abalone shells are found, and the green variety is not so scarce as further north. The shells themselves are often to be picked up on the beach. I remember fans made from a little burrowing owl being sold at Coronado. The wings are spread around the body in a semicircle, and, to say the least, they are pretty souvenirs. The Mexican owls are more expensive.

The red variety of the abalone shell that attracted my fancy was one I found in Monterey. At Santa Cruz seaweeds pressed and grouped on cards seemed common, but they were without interest. A few miles north of Santa Cruz is a group of big trees, and there I secured a square board of the mottled pine with which when polished book covers can be made. I use it as a cover for a portfolio to hold some engravings of the old missions that were purchased in San Francisco.

If there were no other object in view, the magnificent drive of twenty-six miles up Mount Hamilton to the Lick Observatory is worth taking for its delightful experience, to say nothing of the views that are seen as the mountain is ascended. I hope Professor Holden will pardon me if I recall as a souvenir of my visit to Mount Hamilton the print of a photograph of the moon taken at the observatory which he signed for me, and which now hangs in my library, framed crudely in some wood from branches from trees that I cut in descending the mountain.

Chinese curiosities are naturally what are to be found most abundantly in San Francisco. A dirk knife in a carved bone case from Tong Yeun, in Jackson St., is a reminder of a visit to Chinatown, while a knife concealed in an imitation fan is also a trophy from the Chinese quarters. In Oakland it was quite possible until recently to purchase jewelry, such as sleeve buttons and scarf pins, made with thin sections of gold quartz showing the metallic veins set in California gold, and I understand that San Francisco jewelers make some very handsome souvenirs in California gold of different shades for tourists. It is also possible to procure the tiny gold fractional parts of a dollar which were coined at the United States branch mint in San Francisco some years ago. They are no longer made, and certain dates command a premium among numismatists.

There is a Chinese quarter in Portland, Oregon, and there again one may gather curios from the Orient if he so desires. A pack of Chinese playing cards that cost me a trifle, perhaps "two bittee," is the result of an evening's stroll among the haunts of the Celestials. In the vicinity of Puget Sound, as in Tacoma and Seattle, Indian curiosities, chiefly those made by the Indians from Alaska, who come down for a short while during the autumn to pick hops, are to be had. Closely woven baskets, such as those seen in Southern California, are found and also the stone carvings, representing totem poles. In Victoria and Vancouver, in British Columbia, similar curios may be purchased, including spoons made from the horns of buffaloes or perhaps more correctly bisons; also woven mats from Alaska and silver bracelets purporting to be made by the natives, but which are said to be made in Victoria by Indians in order to supply the tourists' demand.

Coming east from the Pacific coast, skins are sometimes procurable, but horns are more common, and frequently a pair of antlers can be picked up from the heaps that are seen in the vicinity of the railway stations. Doubtless here and there bead work can be had, but I failed to find any. It is at Niagara Falls and similar resorts that much of the Indian beadwork made into cushions and the like is to be found.

Indian pipes or calumets made from the mineral catlinite may be bought in the Northwest, and at Sioux City are the works where the agatized wood is cut into slabs, some of which are made into clock faces and the like. These are also to be had in St. Paul. What to look for in Chicago is indeed a question. Relics of the great fire are presumably no longer obtainable, but I well recollect a little bell that purported to be made from the molten metal of the big bells of the City Hall that were common in 1873. Probably souvenirs of the World's Fair held in 1893 would be more easily obtainable. There were many such, and perhaps something has been made from the material of the buildings that were torn down. Exquisite bronzes reproducing in miniature the animals that were conspicuous on the grounds, notably the grizzly bear by Proctor, were made, but they were very expensive. The Columbian half dollars or the Isabella quarters are not bad reminders of the Exposition, and even the tickets of admission, especially those that were so beautifully engraved, are well worth preserving.

At Cincinnati there is the Rookwood Pottery, and its products are everywhere conceded to be exquisite works of art. The "aerial blue" coloring is one of the latest of its many styles and is the most admired by some. The rare Matt Morgan, Kezonta, and Avon wares were also made in Cincinnati, but the potteries where these were produced have long since ceased to exist. Curious pieces of pottery are also to be had in East Liverpool and Steubenville, Ohio. The usual run of curiosities are to be had at Niagara; besides the Indian beadwork already mentioned, birch canoes can be purchased, but most of the articles on sale are from elsewhere, especially the agates. A fossil lingula from the Niagara limestone, found along the line of the river, came to me from the hands of Joseph LeConte, one of the greatest of American geologists, is a souvenir of a visit to the falls with a party of geologists. As we come nearer home I am reminded of a day spent in Utica searching for the American imitations of the old Flemish blue stoneware. Unfortunately, the maker persists in adorning his wares with German legends, but still an interesting collection of "steins" can be procured. In Albany, an enterprising jeweler had made in Austria some articles of the brilliant decorated Hungarian glass, which, even though made in Europe, have designs that recall local events of the times of the Patroons.

In New England souvenirs run largely to pottery. Rare bits of the Chelsea faience are still occasionally to be found in Boston, where also is sold the Longfellow pitcher, which is of English make. The Low tiles from Chelsea are genuine American products. The witch jug from Salem, made at the Hampshire pottery in Keene, is also an American article, while the stranger vases of mottled clay from Gayhead are unique. Curious pipes are also to be had from Cottage City, where the Gayhead Pottery is. Tiles, plates and pitchers abound and are to be had with American views, such as the old tower in Newport or the homes of our New England poets. Here and there are glass factories some of which afford things of interest. The amberine of reddish shaded glass, the Burmese, the Sicilian and the peach blow are among the varieties of interest, none of which are now made, as far as I know, that were found in the show rooms of the glass makers in New Bedford, some years ago, while the old cut glass of Sandwich is held at fancy prices.

No mention of souvenir spoons has been made, and yet the time will come when the better varieties of these will be highly prized by those who were wise enough to collect them when the craze was on. There can be no doubt, it seems to me, that by a judicious selection of the curiosities sold in this country one can fill one's home with interesting "Things American," many of which will recall pleasant visits to various sections of the Union.

THE TOMATO GRAFTED UPON THE POTATO.

The origin of grafting is very ancient. This is not the place to reproduce the history of the art, which is given in special works, but it is likely that man learned it in nature. Who has not seen examples of natural grafting in the woods between the branches or trunks of trees, or the branches of a thick bush?

Nevertheless, as easy as grafting is in many cases, a person who is not up in the art will be amazed upon opening a manual of arboriculture to see the number of varieties of grafts that have been devised by nurserymen and horticulturists, and the knowledge that has had to be acquired in order that the operation may never prove unsuccessful. The great trouble has been and is still to ascertain the affinity between the subject that is to receive the graft and the plant whence the scion is derived. In fact, it is necessary that the anatomical elements of the plants brought into contact

TOMATO GRAFTED UPON THE POTATO.

shall be as similar as possible and that their multiplication shall occur at the same epoch, in order that such elements may unite intimately, and that the graft, firmly fixed, may give the results that are expected from it. Much has been written upon this subject, which is not yet exhausted. However, all are agreed upon one point, and that is that it is indispensable that the plants associated shall belong to the same family, if not to the same genus, in order that the graft may take. If there are any exceptions to this rule, they must be very rare. It is curious to find, even, that some species placed very near each other in classification absolutely refuse to unite, and that the adhesion of others proves of short duration. We may here quote a few remarks from the pen of a master in the art of grafting:

"The explanation of the sympathies and antipathies in the grafting of different species is still wanting. No explanation, either, has been given as to why certain genera can be grafted upon others without the reciprocal being possible. For example, the apple does not succeed upon the pear; while we have seen the latter living for some years upon the former. The pear adopts the quince, and even the white thorn, as a subject, but these plants do not render the same service to their ally. The service, medlar, quince and quickbeam, which are so unlike each other and the white thorn, all sympathize with the latter. The peach and apricot graft upon each other with difficulty, while both succeed upon the almond and plum. All the cherries graft upon the mahaleb, but the latter grafts upon no cherry."

The number of such examples that have been revealed by experiment, but that it is almost impossible to foreknow a priori, might be still further increased.

Grafting has rendered and is still rendering great service in the multiplication of sarmentous plants such as clematises, or, again, of peonies, and even of certain arborescent species which are refractory to propagation by slips; and it is then upon roots that the grafting is practiced, the subjects selected being vigorous species or varieties always belonging to the same genus.

It is also possible to graft annual plants when these have stalks or branches that are sufficiently fleshy, and a striking example of this is shown in the accompanying engraving. It cannot be said, however, that this process has entered into practice, and up to the present it has been merely a matter of curiosity. Carrière, who was a practical man and an indefatigable investigator, tried the most diverse kinds of grafting, and among other results, obtained a crop of tomatoes upon stems of the bitter-sweet. Mr. C. Baltet, an experimenter of

the first rank, has attempted to graft the most diverse plants and has brought together, in a work entitled L'Art de Greffer, very useful directions and advice as to grafting and information as to the species that can be multiplied with certainty by this process.

In grafting branches of the tomato upon stalks of the potato plant, M. Baltet's son has made an interesting experiment that realizes the utile dulci of Horace upon one and the same plant, and which merits being placed before the eyes of our readers, to whom it will show the affinities of two plants belonging to the same order (Solanaceæ) and the possibility of grafting plants which have an ephemeral existence in some regions and which, at first sight, would not seem to be capable of giving so curious results.—La Nature.

THE WEEPING SPRUCE.

OF all our common conifers, the spruce, Picea excelsa, is the most prolific in variations. Some of these are of extraordinary character, some elegant, others ugly. Of pendulous varieties there are several, but none more remarkable than the one figured in our illustration, from a photograph kindly forwarded to us by Mr. A. D. Webster, the superintendent of Greenwich Park. The tree, which measures 30 feet in height, is growing at Ide Hill, Sevenoaks, Kent. We are indebted to the Gardeners' Chronicle for the engraving and particulars.

A WEEPING SPRUCE AT IDE HILL, SEVENOAKS, KENT, ENGLAND.

MARINE PHOTOGRAPHY.

MARINE photography has its peculiar charms. It has also its special difficulties. If the amateur is to derive any satisfaction at all from his "snapshots," he must give a little preliminary study to the nature of the task which he sets himself. It is not enough that he should include among his luggage marked for cabin use, when he boards some oceangoing steamer, or pleasure yacht bound upon a foreign cruise, a two-guinea hand camera with which to secure pictures upon his voyage. With this he may or may not succeed. Chance may favor him or it may reduce him to despair, and he may be tempted to throw up photography as an art which is beyond his aptitude, when, if he only knew the truth, the fault rested rather with the insufficiency of his apparatus than with his want of skill. Success in taking photographs at sea depends very greatly upon an appropriate choice of a camera, and upon what may be termed the modesty of the operator's ambition. Let him first make up his mind what he intends to do, and then let him provide himself with the best possible means of accomplishing his purpose, and, above all, let him not entertain the fancy that with one description of camera he can exhaust the possibilities of marine photography.

The range presented to the devotee of the camera on shipboard is immense. It may be limited to "taking" one's fellow passengers or the sailors, and if it goes no further than this, hand cameras of the customary description may do. But if mere amusement be not the object, if the camera is to serve a really practical and useful purpose, especially if it is to assist the navigator by obtaining permanent records of collision, or damage resulting therefrom, or by securing pictures of coast lines and the like, then something more than a scientific toy is demanded. Intelligent application, and not the mere capricious love of timekilling in an amusing fashion, must stimulate the operator, or he will assuredly fail. And the first thing to recollect is that the photographic lens has a limited vision after all. You have no right to expect of it the wonderful, transcendental powers attributed to the tremendous telescope immortalized by Mr. Weller. It is idle to suppose that it will see with equal distinctness the minute products of deep sea soundings and the distant steamer two miles away. Of course it is possible to strike a happy mean between these two, and the result will be gratification rather than disappointment. But one must bear in mind that short sight and long sight are not reconcilable. If you peer with your camera into the hedgerow, you must not feel aggrieved if it does an injustice to the horizon. And the point is emphasized at sea. One may make certain of a very good negative of the launch of a boat right under the eye, and yet fail to bring two steamers approaching each other within the limits of the plate.

Perhaps marine photographs are especially deceiving, in that they appear to magnify distances. A tugboat plowing its way along one of the reaches of the Thames, as seen in the print, gives one the impression that the camera was at a considerable distance from it; yet, in actual fact, the point of sight was only a few yards removed from the object taken. The difficulty of securing a picture at sea lies in the fact that a considerable space must intervene between the object and the operator, whereby everything is so much dwarfed.

The Diamond Jubilee Review afforded interesting proof of this contention. Various efforts were made to get a satisfactory photographic record of the great naval display, but they have all failed. Perhaps the most successful have been the panoramic pictures obtained by composite printing; but it must always be recollected that a panorama can never be regarded as one picture—it is a series of subjects placed in consecutive order. People who have gone to animated photographic displays with the expectation of enjoying some picture of the review in its entirety have been disappointed. They have come away with a very fair notion of individual battleships, with the incidents around them, such as the passing of a yacht, guard boat, or excursion steamer, but they have not been given a comprehensive idea of the whole fleet. It has been left to the imagination of artists to limn the scene as they supposed it to be, not as they saw it themselves; for the human eye is less powerful than the lens, and where the latter falls short it cannot be supposed that the naked vision can succeed.

As an example of what can be done by the photographer, the work of a clergyman may be instanced. Into one of his pictures of the naval review he did squeeze from twenty to thirty warships. His plate was 10 inches by 8 inches and he was compelled to station himself two miles off, and to use a telephoto attachment, which enlarged each object five diameters—that is, five times. Yet, in the print, all his ships are extremely small—not more than ⅝ inch in length; and if he had used a ¼ plate camera, they would not have been ⅛ inch in size.

It may be gathered from this that it is of not much use to attempt to photograph at a great distance. Yet what is two miles to a vessel going eighteen knots an hour? It is a matter of a few minutes' steaming only, and anyone who may attempt a sketch of a rugged coast from the deck of an approaching steamer, traveling at any rate, will at once perceive how in a few seconds the picture changes so as to be completely altered from the moment that the first stroke of the outline was drawn. Say, for instance, you are steaming toward Corbière Lighthouse from Jersey. The headland from which it juts out acquires a different form as you draw nearer, and the pyramid rocks themselves gain not only in definition, but change their shape as the course of the steamer alters on its way to Guernsey. These transformations are so rapid that only an instantaneous view can take note of them; yet, from the artistic standpoint, there is but one crucial moment when the picture of the Corbière is at its best, and it is precisely at that instant it should be "snapped."

Makers of photographic instruments are, of course, fully alive to the requirements of the marine photographic artist. It was from one well known firm—Messrs. William Watson & Sons, of 313 High Holborn—that Mr. A. Debenham, of Ryde, procured the 18 inch by 16 inch rapid rectilinear lens with which he took the magnificent picture of the Prince of Wales' yacht "Britannia," racing at full speed; and the same makers have, at different times, supplied other photographers, many of them of high social standing, who have turned their attention specially to this branch of the art. Among them may be named the late Lady Brassey and her daughter Beatrice, from whose negatives the Voyage of the "Sunbeam" was illustrated. Lady Brassey's method was this. She sat on deck in a chair, and a very heavy upright pole, 5 inches in diameter, something resembling that of a surveying instrument, was fitted into a socket in the deck, and on the top a mechanical arrangement, into which the camera was screwed, always kept the camera square in front of her, however much the boat might rock.

It may be taken for granted that a tripod cannot be used on board ship; the vibration is too great; although Captain Owen, late of the Union Steamship Company, has, I believe, employed one amidship, but only on exceptionally fine days and when the sea has been quite smooth. This officer is unrivaled in his yachting pictures, some of which may be seen at the Imperial Institute. It is his plan to sit in a little cabin on his yacht, and by mechanical means he can turn himself round to any point of the compass, so that he can always keep the yacht that he may be following in the field of his lens, until the supreme moment arrives for snapping it.

The question may naturally be asked, "When can the snapping time be determined?" Of course the use of "finders," as they are called, is well understood, but there are finders and finders. Mr. Debenham, as he goes about in his stout little dingey, often uses an ordinary finder, but Captain Owen, when he works on a large scale—i. e., with plates 10 inches or 12 inches square—employs a double camera. The two cameras are mounted on one baseboard, side by side. They have one focusing screw and one traveling frame, so that the coincidence is accurately kept. The view is watched in the left camera, which is hence the finder, and an exposure is made in the right just at the moment that the picture is perfect. In this finder the operator sees the object exactly under the same conditions as the companion camera secures it on the plate, which is a great advantage.

But amateurs who have not such serious work in mind may be content with a less elaborate apparatus. Watson's double camera has also twin lenses, but placed one above the other and not side by side. The finder is uppermost. When you raise the hood you see the image, full size, reflected upon a sheet of ground glass at the top of the camera by a mirror placed at right angles to the lens. This camera has also the advantage of permitting the operator to watch and wait for the most appropriate moment of exposure, when he squeezes the pneumatic ball, the use of which insures steadiness, and the trick is done. Hitherto, the principal drawback of a double camera has been the bulk, but this pattern is very little larger than an ordinary camera. Its dimensions for the half-plate size are 8¼ by 9 by 10, and weight complete 9 pounds. It is particularly adapted for use in the hand, and its great advantage is that the object can be focused up to the moment of exposure with absolute certainty of result. Such a camera, therefore, can be confidently recommended for work on board ship. Nothing is left to chance. You see your picture as you take it.

Now, is there any reason why this camera should not be further adapted for marine pictures? These are apt to be long and narrow, especially where long focus lenses are used. It would be an advantage in photographing a coast line, or a seascape, to use a 7½ inch by 5 inch horizontal plate; but this modification would involve an increase of bulk and weight. This consideration, however, might at sea be dismissed as of secondary importance. Of far greater necessity on board a large ship—it is not so essential on a yacht—is the long focus lens; and in the building of a camera specially suitable for marine work care should be taken that such lenses are included in the outfit. But you cannot expect them to do duty when snap shotting your fellow passengers. It would be as unreasonable as to use field glasses for reading an evening paper under your eyes.

The still less aspiring amateur, who does not aim at making long focus pictures a specialty, may very well be content with the lighter and inexpensive Vanneck hand camera, which has but one lens. The view finder is in the middle of the top of the box, and shows the same picture as is being taken on the sensitive plate, less the margin of the plate. The one lens is so arranged that when the image is seen sharply it is necessarily in focus on the plate. A turn of a screw immediately sets any object seen, near or distant, into perfectly sharp focus. With this camera you may use in one size a 4¼ by 3¼ inch glass plate or cut celluloid film, which is preferable to a roll film, or one of 3¼ by 3¼ inches. A dozen sensitive plates are contained in a holder at the back of the box, and at the top of the reservoir is a flexible bag into which the plate is raised by a lever, and thence lifted to the front ready for exposure when the spring is pressed. The Vanneck is most suitable for all general hand camera work, and, with an outer leather case, especially recommends itself to travelers.

One thing, in conclusion, must be borne in mind. Cheap cameras are usually costly in the end, and a good camera is worth its price.—J. H. Richardson, in Nautical Magazine.

A NEW STEAM PROPELLED AEROPLANE.

THE French Academy of Sciences recently received a description of an air ship constructed by Messrs. V. Tatin and Charles Richet. This new apparatus considerably exceeds Prof. Langley's aerodrome in size and speed. Langley's apparatus weighed about 22 pounds, and a speed of over 12 yards per second was obtained. The Frenchmen have produced an apparatus weighing 73 pounds and developing a speed of about 20 yards per second. The figures given include a water supply of 3 liters (weighing about 6½ pounds) and 900 grammes (about 1¾ pounds) of coal, sufficient for a flight of 5 kilometers, or a little more than 3 miles. So far, however, the longest flight has been only 140 meters (153 yards), the apparatus having a strong tendency to take headers. In this respect it is distinctly inferior to Langley's. The new apparatus cannot be experimented with except in perfectly calm weather, and even then it was necessary to start the machine on an absolutely horizontal flight, or it would tip over and come down suddenly.

The aeroplane consists of a very light frame of thin wood covered with silk. Attached to this frame are two fixed wings of like construction and of an area of 14½ square yards. The wings are connected with the body by steel wire. The machine further has a tail made of a wood frame and silk covering. A steam engine is used to drive two screw propellers, one of which is placed fore and the other aft, the two screws rotating in opposite directions.

To start the apparatus, it is placed on a car rolling down an inclined plane of 92 yards length and 11 yards height. At the end of the inclined plane an automatic appliance severs the connection between the car and the aeroplane, and the latter then proceeds on its free flight. The inventors are continuing their experiments, particularly in order to improve the conditions of equilibrium in their machine, and they hope to secure much better results when improvements have been made.—Der Stein der Weisen.

INCREASE OF RAIN IN MODERN TIMES.

"ACCORDING to M. Camille Flammarion," says the Literary Digest, which translates from La Génie Moderne, "who has compared all the hydrometric observations made at the Paris Observatory for about two hundred years, the amount of rain that falls in our regions is increasing yearly. This increase may be seen at the first glance by examining the averages of different periods. From 1689 to 1719 there fell an average of 485·7 millimeters [19·3 inches] of water.

" From 1720 to 1754	409·4
" 1773 " 1779	492·5
" 1804 " 1824	563·7
" 1825 " 1844	507·5
" 1845 " 1872	522·4
" 1873 " 1896	557·4

"It is certain that the year 1897 will be fully up to any of its predecessors in the matter of rain. The rainfall is increasing, then, at Paris, from period to period. To avoid this moist conclusion, we must maintain that the old observations were made carelessly. But—at the Paris Observatory! the thing is inadmissible! It would be interesting to compare with these numbers the heights of the Seine and the dates of its inundations. But, on the other hand, the modern construction of quays, the part played by the dams and weirs erected by our engineers, as well as the precautions taken against sudden rises, bring in an element foreign to meteorology, whose exact share in the results it would not be easy to confute."

LAST ISSUE OF THE YEAR—RENEWAL SUBSCRIPTIONS NOW DUE.

WE take this opportunity to remind our old friends and readers that with this issue many subscriptions will expire, and, in order to prevent any break in the receipt of the paper, it is advisable to remit for the new year without delay, and we also believe that those who are not receiving the SCIENTIFIC AMERICAN would find themselves repaid by subscribing for this journal also, and getting the advantage of the combined rates.

TERMS.

The Scientific American (weekly), one year	$3.00
Supplement of the Scientific American (weekly), one year	5.00
Building Edition of the Scientific American (monthly), one year	2.50
Export Edition of the Scientific American (monthly) in Spanish and English, one year	3.00

COMBINED RATES.

The Scientific American and Supplement	$7.00
The Scientific American and Building Edition	5.00
The Scientific American, Scientific American Supplement, and Building Edition	9.00

This includes postage, which we pay. Foreign subscribers should remit one dollar extra for postage on each publication. Remit by postal or express money order or check to order of Munn & Company, 361 Broadway, New York.

THE

Scientific American Supplement.

PUBLISHED WEEKLY.

Terms of Subscription, $5 a Year.

Sent by mail, postage prepaid, to subscribers in any part of the United States or Canada. Six dollars a year, sent, prepaid, to any foreign country.

All the back numbers of THE SUPPLEMENT, from the commencement, January 1, 1876, can be had. Price, 10 cents each.

All the back volumes of THE SUPPLEMENT can likewise be supplied. Two volumes are issued yearly. Price of each volume, $2.50 stitched in paper, or $3.50 bound in stiff covers.

COMBINED RATES.—One copy of SCIENTIFIC AMERICAN and one copy of SCIENTIFIC AMERICAN SUPPLEMENT, one year, postpaid, $7.00.

A liberal discount to booksellers, news agents, and canvassers.

MUNN & CO., Publishers,
361 Broadway, New York, N. Y.

TABLE OF CONTENTS.

The Scientific American Supplement. Index for Vol. 44.

JULY–DECEMBER, 1897.
